There is a marked awareness of the need for more knowledge. H. S. D. Garven[7] calls for more studies of the normal in the Chinese subject. There is as yet little or no knowledge of the limits of variability of many of the simple, easily measurable characteristics both anatomical and physiological in Chinese. Some studies have been made, but the figures available for varying social class, locality, occupation, climate, and diet are as yet quite meager. Such data must be forthcoming as a basis for all health work.

In the same issue of the *Chinese Medical Journal,* the editor proposes a study, along the lines suggested by Garven, of the physical, physiological and mental development of one group of Chinese, the Cantonese.[8]

Information of the type contained in these two proposals is offered by Chen-Chia Lee.[9] A statistical study of 3,550 full term infants born in West China showed an average weight at birth of 3,080 grams, irrespective of sex. The average for boys is 100 grams more than for girls. These birth weights were correlated with the season, and with the age, parity, and nutritional status of the mother. The mother's nutrition seemed to make little difference in the birth weight. On the other hand, it appears that infants born in the winter and spring are heavier than those born during other seasons. Infants born in West China are reported to be smaller than those born in North and Central China, but heavier than Cantonese babies.

Trachoma is one of the common chronic diseases in China and one of China's most important medical and public health problems. Chen-Chung Wu reports on trachoma in Changsha on the basis of hospital statistics.[10] Of 1,340 patients attending the eye clinic of the Hsiang-Ya Hospital at Changsha 1,017 (75.8 per cent) suffered from trachoma. The highest age incidence was between 10 and 40 years of age. Occupational incidence for this group was found to be highest among students and teachers, merchants, coolies, and housewives respectively. It should be noted that the apparent higher incidence among teachers and students is probably due to the fact that they come for examination and treatment as soon as any symptoms are noted. Similarly, merchants come because they can well afford the treatment.

Flowers[11] discusses the causes of blindness in China and links this problem to the greater one of raising the standard of living and education among the Chinese people. He points out that most of the blindness in China has direct and indirect causes. These he lists as follows:

Direct Causes	*Indirect Causes*
1. Smallpox	Lack of vaccination
2. Trachoma	Poverty, dirt, low standard of hygiene
3. Ophthalmia neonatorum	Poor midwifery
4. Phlyctenular conjunctivitis	Poverty, low standard of living
5. Keratomalacia	Dietary deficiency
6. Ulcerative keratitis	Poverty, ignorance, poor hygiene, low standard of living
7. Mucopurulent conjunctivitis	

Flowers concludes that an attack upon the vast problem of blindness in China must therefore include adequate medical treatment plus the greater general task of public education, including health education.

DECLINING MORTALITY IN WESTERN EUROPE AND THE UNITED STATES

Examination of the general mortality rate for various countries shows that a significant decline has occurred since the middle of the last century.[12] Comparison of the figures for the period 1841–1845 with those for 1945 reveals a drop for France from 227 to 156 per 10,000 inhabitants, for Belgium from 235 to 147, for Holland from 239 to 151, for Denmark from 196 to 105, and for England from 214 to 126. Moine emphasizes that between the decade 1846–1855 and the year 1936 the risk of death for persons of all ages has dropped to 69.9 per cent of its initial value for males and to 60.4 per cent for females. This decline is due particularly to the mortality changes in the younger age groups, and is attributed by Moine to advances in preventive and therapeutic medicine as well as in social welfare.

When mortality is examined by cause, it is found that in France from 1907 to 1936 the number of deaths due to tuberculosis, other communicable diseases, and diseases of the digestive and respiratory systems has declined, while the deaths ascribed to diseases of the cardiovascular, nervous and urogenital systems, cancer, and senility have risen. As an example Moine takes tuberculosis, comparing the periods 1889–1893 and 1934–1938. This comparison shows that for males the deaths from tuberculosis fell to 89 per cent of the initial value (174 to 155) and for females to 83 per cent (130 to 108).

In another study Moine pursues his analysis of mortality by comparing mortality in France and in the United States.[13] He points out that there has been a marked decrease since 1900. In the United States this decline is notable particularly in the case of such causes as the enteric diseases and diphtheria. On the other hand, increase in cancer, cardiovascular diseases, diabetes, and accidents presents a serious problem. A striking difference between France and the United States is the number of deaths attributed to senility, 8.9 per 10,000 in the United States and 193 per 10,000 in France. It is not unlikely, however, that this difference is due in part to better diagnosis and reporting in the United States. France also has a larger number of deaths attributed to tuberculosis and diseases of the respiratory system (+ 111 per cent and + 61 per cent per 100,000 population respectively). On the other hand, France has fewer deaths ascribed to cardiovascular disease and to diseases of the urogenital tract.

STILLBIRTHS AND MORTALITY OF PREMATURES IN RUMANIA

As part of an investigation of the sanitary environments of middle and lower class urban women, Slobozianu studied 24,000 births recorded from 1916 to 1942 in the First Obstetrical Clinic, Filantropia Hospital of Bucharest.[14] In rural areas the stillbirth rate has been 2.2 per cent, while in urban districts it has been 5.3–5.5 per cent and in some cities even 8.9 and 10.67 per cent. In the Obstetrical Clinic the stillbirth rate from 1921 to 1924 was 4.7 per cent, while from 1937 to 1942 it was 8.2 per cent, which is in agreement with the general increase observed throughout Rumania.

Premature mortality was 3.7 per cent in rural areas and 3–3.1 per cent in towns. In the clinic it was found to be 2.45 per 100 live births. Syphilis was found in 16.1 per cent of premature births that occurred in the Obstetrical Clinic between 1921 and 1924, and in 18.21 per cent of those during the period

1937–1942. To alleviate the situation, Slobozianu recommends the improvement of obstetrical practice, increased prenatal care including social assistance to needy mothers, and special attention to the treatment of syphilis in pregnant women.

Rumania is at present considerably concerned with improving the "biological capital" of the country, that is, its population.[15] One of the problems involved is that of abortion. In view of the large number of abortions that are performed and the serious consequences that these have, it is suggested that the legislation of abortion be revised. Crainicianu and his collaborators suggest that in addition to therapeutic and eugenic indications for abortion, place be reserved for a social indication. The author proposes the establishment of a commission attached to certain hospitals which would establish in each case the need for intervention. This would be a transitory measure to be abandoned as soon as the economic and social conditions in Rumania will permit the institution of effective measures of social assistance to mothers and infants.

The similarity of this proposal to actual practice in the Soviet Union in the years immediately following the revolution is readily apparent. It will be worth observing Rumanian developments to see to what extent these will parallel the Russian experience.

ASSOCIATION NEWS

SEVENTY-SEVENTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
NEW YORK, N. Y., OCTOBER 24–28, 1949

ROSTER OF SANITARY AND PUBLIC HEALTH ENGINEERS

The following is of importance to all sanitary and public health engineers:

Efficient utilization of our national resources, both human and otherwise, is difficult during periods of national emergency. Criticism has been directed against the federal government and its agencies for the inefficient use of sanitary and public health engineers during World War II.

The National Security Resources Board is charged with the responsibility of planning for the efficient use of our national resources in any emergency. James A. Crabtree, Medical Director, U. S. Public Health Service, has been assigned to the NSRB to develop methods for the best utilization of medical and public health personnel and facilities. One of the first goals of Dr. Crabtree's Medical Division is the preparation of comprehensive rosters of professional personnel. Should another national emergency arise, these rosters will be used in developing programs that will assure the best use of all professional people.

Arrangements have been made with the American Public Health Association, through the Engineering Section Project, for the preparation of a roster of all sanitary and public health engineers in the United States, other than those in federal service. The magnitude of this task can be appreciated when it is realized that there is no comprehensive list available similar to the membership list of the American Medical Association, the American Nursing Association, or the American Dental Association. Neither are there state professional registers such as exist for physicians, nurses, and dentists.

Lists of engineers are now being prepared from membership lists of the various professional and technical societies. The Conference of State Sanitary Engineers has volunteered its active support and assistance. Other organizations and even individuals are being asked to help. Questionnaires will be sent out to individuals in the near future. Prompt return of the forms is requested. It will be to the advantage of each engineer to assure his proper classification so that proper use of his training and experience can be obtained. Any engineer not receiving a questionnaire by July 1 should communicate directly with the

Engineering Section Project
American Public Health Association
1790 Broadway
New York 19, N. Y.

so that his name can be entered on the roster and he be furnished with a copy of the questionnaire.

Undoubtedly there are individuals professionally qualified in sanitary or public health engineering who are not now actively engaged in that field. Since they may not belong to any of the more important professional or technical engineering societies they may not see this notice. You are urged to advise the Engineering Section Project of the names and addresses of such people.

GLOSSARY—WATER AND SEWAGE CONTROL ENGINEERING

After 12 years of preparation, the *Glossary—Water and Sewage Control Engineering* will be ready for distribution by early April. This volume has been prepared by a joint committee composed of representatives of the A.P.H.A., American Society of Civil Engineers, American Water Works Association, and the Federation of Sewage Works Associations. Originally, two Association committees participated in the preparation of the *Glossary*. The first, preparing water works terms, consisted of

Earle B. Phelps, *Chairman*
Sol Pincus, C.E.
Ralph E. Tarbett, C.E.

The second, assigned the preparation of sewage works terminology, consisted of

Gordon M. Fair
H. A. Whittaker

A final review committee, composed of a representative from each sponsor organization, brought the two lists of terms together and prepared the final report. Sol Pincus represented the A.P.H.A. on this committee.

Everyone who uses water or sewage control engineering terms will find the *Glossary* invaluable in preparing reports, articles for publication, or in speaking to professional groups. Widespread use of the accepted definitions should eliminate differences in the use of technical terminology.

The volume, almost 300 pages in length, is available to A.P.H.A. members through the Association Book Service at $1.00 per copy. A cloth-bound edition will be available at $2.00 a copy. Order your copy now to be sure you get it without delay. Non-members may order directly from the American Society of Civil Engineers, 29 W. 39th St., New York City, $2.00 for paper-bound, $3.00 for the cloth-bound volume.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Pierre A. Belanger, M.D., D.P.H., 33 Main St., West, Hawkesbury, Ont., Canada, Director, Prescott and Russell County Health Unit

Thomas DeAngelo, Health Department, Perth Amboy, N. J., Acting Health Officer

Manly B. Donaldson, M.D., D.P.H., City Hall, Westmount 6, Que., Canada, Medical Officer of Health

George B. Foster, Jr., M.D., Dr.P.H., Cambridge City Hospital, Cambridge 39, Mass., Medical Director

Romeo G. Grenon, M.D., D.P.H., Casselman, Ont., Canada, Asst. Medical Officer of Health, Prescott and Russell County Health Unit

Henry W. Lane, M.D., Box 228, El Dorado, Kans., Director of Public Health for Butler County

Lorne A. MacLean, M.D.C.M., D.P.H., Undercliff Sanatorium, Meriden, Conn., Staff Physician

Yukiharu, Miki, M.D., Public Health Bureau, Ministry of Welfare, Tokyo, Japan, Chief, Public Health Bureau

William R. Ross, M.D., City Hall, Tyler, Tex., Director of Public Health, Tyler-Smith County Health Unit

David Trainer, M.D., 1005 South Cordova Ave., Alhambra, Calif., Communicable Disease Physician, Los Angeles County Health Dept.

Laboratory Section

Norman S. Argue, 900 Creek Drive, Annapolis, Md., Laboratory Asst., Sanitation Research Project, Association of American Railroads

Robert S. Lloyd, M.S., 1103 W. Pratt, Baltimore 23, Md., Bacteriologist, Sanitation Research Project, Association of American Railroads

Camille May, 221–14th St., N.E., Atlanta, Ga., Medical Technician, Communicable Disease Center, U. S. Public Health Service

Rafael A. Osorio, D.V.M., Apartado Postal

No. 18-76, Mexico, D.F., Mex., Medico Veterinario, Casa Sanitaria Ganadera y Agricola

Robert A. Patnode, M.S., 605 Volunteer Bldg., Atlanta, Ga., Bacteriologist, Tuberculosis Evaluation Laboratory, Communicable Disease Center, U. S. Public Health Service

Roland S. Shumard, 1700 South Second St., St. Louis, Mo., Coordinator of Disinfectant and Industrial Preservative Development, Monsanto Chemical Co.

Sara M. Stanford, 1035 Euclid Ave., N.E., Apt. No. 1, Atlanta, Ga., Medical Technician, Communicable Disease Center, U. S. Public Health Service

Paul B. Wise, 1010 Greenwood Ave., Maywood, Ill., Medical Technician, Veterans Hospital, Hines, Ill.

Statistics Section

Stanley Glaser, 52-A Ridge Rd., Greenbelt, Md., Statistician, Tuberculosis Control Division, U. S. Public Health Service

Nathan Keyfitz, 5 Bristol Ave., Ottawa, Ont., Canada, Mathematical Advisor, Dominion Bureau of Statistics

Arthur Lenz, 1438 Ocean Ave., Brooklyn 30, N. Y., Senior Statistician, New York City Dept. of Health

Marie A. Martens, 23 Carolina St., Charleston 20, S. C., Senior Clerk, Charleston County Health Dept.

Sidney M. Norton, Bureau of Vital Records, City Health Dept., Baltimore 3, Md., Director of Bureau

Sarah E. Shanks, M.S., 210 North Denver St., Jackson, Miss., Statistician, State Board of Health

Ada L. Smith, 1936 Green St., Harrisburg, Pa., Biometrician, Cancer Control Division, State Dept. of Health

Mildred A. Whitmore, 34 St. and Curie Ave., Philadelphia, Pa., Medical Record Librarian, Philadelphia General Hospital

Engineering Section

Marshall P. Crabill, 113 Monument Circle, Indianapolis, Ind., Supt. of Purification, Indianapolis Water Co.

Frederick K. Erickson, S.M., State College of Washington, Pullman, Wash., Asst. Professor of Civil Engineering and College Sanitary Engineer

John J. Foley, 168 No. Boulevard, Salisbury Beach, Mass., Student, Univ. of Massachusetts

F. E. Gartrell, M.P.H., 12 Sheridan Ave., Chattanooga 4, Tenn., Chief, Central Services Section, Division of Health and Safety, Tennessee Valley Authority

Arnold E. Greenberg, M.S., Massachusetts Institute of Technology, Cambridge 39, Mass., Research Asst., Dept. of Civil and Sanitary Engineering

Armando A. Hidalgo A., Dr.C.E., Sur 3-No. 7-M.S.A.S., Caracas, Venezuela, S. A., Asst. to Director, Division of Sanitary Engineering, Ministry of Health

Carl E. Shell, P. O. Box 55, Mocksville, N. C., Senior Sanitarian, Davie, Stokes, Yadkin District Health Dept.

Robert L. Stein, M.S., Tela Railroad Co., La Lima, Honduras, C. A., Soils Engineer, Engineering Dept.

Luciano C. Vareda, M.S., Reparticao de Saneamento, Joao Pessoa, Paraiba, Brazil, S. A., Manager, Waterworks and Sewage System

Industrial Hygiene Section

George S. Baldry, M.D., D.P.H., 198 Beach St., Quincy 70, Mass., Plant Physician, Hood Rubber Co.

Crawford E. McLain, M.D., Champion Paper & Fibre Co., Canton, N. C., Plant Physician

Clarence N. Overcash, Box 754, West Lodge, Ypsilanti, Mich., Student, School of Public Health, Univ. of Michigan

Food and Nutrition Section

Maurine Dillon, M.S., 507 Carondelet St., New Orleans, La., Consultant on Nutrition, City Health Dept.

Stephen L. Fielder, M.D., 7-37th Place, Long Beach 3, Calif., Private Practice

Lloyd J. Salathe, 236 Harding St., New Orleans 21, La., Sanitarian, American Institute of Baking, Chicago, Ill.

Ruth E. Tucker, Ph.D., Rhode Island State College, Kingston, R. I., Assoc. Professor of Foods and Nutrition

Maternal and Child Health Section

Edwin M. Gold, M.D., 185 Ocean Ave., Brooklyn 25, N. Y., Senior Obstetric Consultant, New York City Health Dept.

Harry B. Silver, M.D., 11010 Braddock Drive, Culver City, Calif., District Health Officer, Los Angeles County Health Dept.

John T. Smedley, M.D., 800 Dade County Court House, Miami, Fla., Director, Maternal and Child Health Dept., Dade County Health Unit

Public Health Education Section

Everett T. Aultman, M.P.H., Rutherford Health Dept., Murfreesboro, Tenn., Health Education Coordinator

Ellen L. Boyce, Rm. 210, 911 Locust St., St. Louis 1, Mo., Exec. Secy, Tuberculosis and Health Society of St. Louis

Genevieve Burton, R.N., M.P.H., Gibsonville, N. C., Field Secy, North Carolina Congress of Parents and Teachers

Constance I. Cavender, M.P.H., 870 Santa

Barbara Rd., Berkeley, Calif., Public Health Educator, Alameda County Health Dept.

Olga Corser, Mamey a Monzon No. 34, Caracas, Venezuela, S. A., Health Educator, Ministry of Health

George G. Cox, 1039 H. St., Fresno, Calif., Sanitarian, Fresno County Health Dept.

Ruth Dart, M.P.H., Forrest County Health Dept., Hattiesburg, Miss., Health Educator

James J. Holihan, Jr., 16 E. 203 St., Shanks Village, Orangeburg, N. Y., Health Educator in Training, State Dept. of Health

Grace C. Hopkins, 1913 Tyler St., Amarillo, Tex., Exec. Secy., Potter County Medical Society Tumor Clinic

James E. Huddleston, M.S., 250 E. 105 St., New York 29, N. Y., District Secy., Health Council of Greater New York

Rosemary K. Keane, 207 State St., Schenectady, N. Y., Exec. Secy., Schenectady County Committee on Tuberculosis and Public Health

Ruth Kramarow, M.S., 22 Rutgers St., New York 2, N. Y., Health Educator in Training, State Committee on Tuberculosis and Public Health, State Charities Aid Assn.

Russell F. Larson, P. O. Box 30, Leland, Ill., Graduate Student, School of Public Health, Univ. of Michigan

T. G. Raley, 1941 W. Front St., P. O. Box 278, Selma, Calif., Manager, Consolidated Mosquito Abatement District

Buel F. Reagan, M.S., School of Public Health, Univ. of Michigan, Ann Arbor, Mich., Student

Elizabeth T. Roach, 109 East 9th St., Fort Worth 2, Tex., Exec. Secy., Tarrant County Unit, American Cancer Society

Alice Van Landingham, 201 Gordon St., Morgantown, W. Va., Public Health Educator, Monongalia County Health Dept.

Clessie Waddell, R.N., 411½ East Seventh St., Texarkana, Ark., Exec. Secy., Bowie-Miller Counties Medical Society Tumor Clinic

Mary Weeks, M.A., 600 Lexington Ave., New York 22, N. Y., Headquarters Secy. for Health Education and Camping, Y.W.C.A.

Public Health Nursing Section

Mary M. Chopek, R.N., 321 Center St., Iowa City, Iowa, School Nurse, St. Mary's and St. Patrick's School

Matilda B. Glenn, R.N., 306 S. Penn St., Wheeling, W. Va., Orthopedic Field Nurse, State Dept. of Public Assistance

Elsie D. L. Gravdahl, R.N., 920–77 St., Brooklyn, N. Y., Student, New York Univ. School of Education

Marie F. Hanzel, R.N., U.S.P.H.S. Diabetes Unit, P. O. Box 210, Jacksonville, Fla., Public Health Nurse

Frances E. MacFadyen, R.N., 15 Gifford Drive, Worcester, Mass., Field Representative, Bay State Society for the Crippled and Handicapped

Margaret L. Murphy, R.N., 58 South St., Biddeford, Me., Public Health Supervisor, Biddeford Public Nursing Health Assn.

Geraldine M. Newell, R.N., 420½ W. Walnut, Columbus, Kans., Public Health Nurse, Cherokee County Health Dept.

Doris L. Robinson, R.N., 535–32 Ave., San Francisco, Calif., Director of Public Health Nursing, City Health Dept.

Ethel A. Wilkins, R.N., 534 Elm St., Columbus, Kans., Public Health Nurse, Cherokee County Health Dept.

Loretta B. Wilson, 538 S. Minnesota, Columbus, Kans., Public Health Nurse, Cherokee County Health Dept.

Epidemiology Section

Harriet F. Bichler, 3300 Second Ave., Richmond, Va., Junior Statistician, Venereal Disease Control Division, State Health Dept.

Alfred S. Bogucki, M.D., M.P.H., Philadelphia General Hospital, 34 St. & Curie Ave., Philadelphia 4, Pa., Chief, Division of Preventive Medicine

School Health Section

Ruth L. Beidelman, 235 S. Washington, Naperville, Ill., School Nurse, Aurora Board of Education

Frank B. Dugan, M.A., 1033 S. 10th, Edinburg, Tex., Instructor of Physical Education, Edinburg Junior College

Beth Hart, 81 Puritan Ave., Highland Park 3, Mich., Health Teacher, Board of Education

Alice MacCormick, 414 South 41 St., Philadelphia 4, Pa., School Nurse, Darby Boro Schools

Malcolm J. McLelland, M.S.Ed., Indiana Univ., Bloomington, Ind., Instructor and Administrative Asst. to Dean, School of Health, Physical Education and Recreation

Lorenzo A. Remy, M.D., 536 Grattan Chicopee Falls, Mass., Medical Examiner, Metropolitan Life Insurance Co.

Sara L. Smith, M.A., State Department of Education, Tallahassee, Fla., Consultant, Health and Safety Education

Dental Health Section

Ronald D. Frederick, M.A., 2115 Key Blvd., Apt. 967, Arlington, Va., Public Health Representative, U. S. Public Health Service

Francisca Guerra-Alvarez, D.D.S., 22 Jobo St., Ponce, P. R., Dental Director, Department of Health

Donald McGregor, D.D.S., Brighton, Mich., Practising Dentist

William E. McKissack, Jr., D.D.S., 310 La-

conte St., Jackson, Tenn., Dental Health Officer, State Health Dept.

Medical Care Section

Harold Aaron, M.D., 17 Union Square West, New York 3, N. Y., Physician, Consumers Union of U. S.

Jane Airth, R.N., 1636 Bush St., San Francisco, Calif., Educational Director, Visiting Nurse Assn.

Lily Baral, M.S., 613 W. Montgomery, Rockville, Md., Medical Social Consultant, Montgomery County Health Dept.

Thomas J. Berret, UMWA, Area Medical Office, 235 Franklin St., Johnstown, Pa., Administrative Asst., Medical, Health and Hospital Service, Welfare and Retirement Fund, UMWA

Otis Brubaker, Ph.D., 1500 Commonwealth Bldg., Pittsburgh, Pa., Research Director, United Steelworkers of America

John M. Brumm, A.M., Univ. of Illinois, Urbana, Ill., Asst. Professor, Institute of Labor and Industrial Relations

Ruth E. Burcham, B.N., 1636 Bush St., San Francisco, Calif., Exec. Director, Visiting Nurse Assn.

Wilbur J. Cohen, 9819 Capitol View Ave., Silver Spring, Md., Technical Adviser to Commissioner for Social Security, Social Security Administration

John F. Crane, 528 Market St., Paterson 3, N. J., Director, Paterson General Hospital

Ursula Curry, M.S., 5 Concord Ave., Cambridge, Mass., Medical Social Consultant, State Dept. of Public Welfare

E. H. Cushing, M.D., 2320 Tracy Place, N.W., Washington, D. C., Asst. Medical Director for Research and Education, Veterans Administration

Anthony J. DeLuca, Menorah Hospital, Kansas City, Mo., Administrative Intern

Daniel H. Deyoe, M.D., Bassett Hospital, Cooperstown, N. Y., Superintendent

Geneva Feamon, R.N., M.A., 3420–16th St., N.W., Washington 10, D. C., Technical Welfare Specialist, Bureau of Public Assistance, Federal Security Agency

Arnold M. Geiger, D.D.S., 2 East 54th St., New York, N. Y., Dentist

John J. Griffin, 57 School St., Somerville, Mass., Supervisor of Old Age Assistance, City of Somerville

Robert E. Harding, 3025 Hillegass Ave., Berkeley 5, Calif., Student, Univ. of California

G. Halsey Hunt, M.D., 8517 Rosewood Drive, Bethesda 14, Md., Asst. Chief, Division of Hospitals, U. S. Public Health Service

Melvin B. Kirstein, M.D., 539 North Grand Ave., St. Louis, Mo., Medical Director, Garment Industry Medical Center

Sidney Liswood, M.B.A., 330 Brookline Ave., Boston 15, Mass., Asst. Director, Beth Israel Hospital

Catherine F. Lott, Oxford, Md., Medical Social Consultant, Caroline and Dorchester County Health Dept.

Margaret H. Lyman, New York Univ. Medical Group, 463 First Ave., New York 16, N. Y., Asst. to Director

G. M. Mackenzie, M.D., State Laboratory, New Scotland Ave., Albany, N. Y., Division of Laboratories and Research, State Health Dept.

Ray C. Mork, P. O. Box 847, Morgantown, W. Va., Asst. to Area Medical Administrator, Medical, Health, and Hospital Service, United Mine Workers of America

Leo Perlis, 1776 Broadway, 15th Fl., New York, N. Y., National Director, National CIO Community Services Committee

Susan R. Pincoffs, R.N., 5110 Frederick Ave., Baltimore, Md., Asst. Director, Medical Care Clinic, Univ. of Maryland

Harold A. Press, M.D., 5612 Oakmont Ave., Bethesda, Md., Director, Management and Planning Staff, Dept. of Medicine and Surgery, Veterans Administration

Claire F. Ryder, M.D., 8 Beacon St., Boston 8, Mass., Epidemiologist, Bureau of Hospital Survey, State Dept. of Public Health

Robert V. Sager, M.D., 285 Central Park West, New York 24, N. Y., Member, Exec. Committee, Central Manhattan Medical Group

Harold M. Shorr, M.D., 315 West 86th St., New York, N. Y., Medical Director, New York Univ. Medical Group

Hugh B. Speir, M.A., 3383 S. Stafford St., Arlington, Va., Hospital Program Representative, District 2, U. S. Public Health Service

Bernhard J. Stern, Ph.D., Fayerweather Hall, Columbia Univ., New York 27, N. Y., Lecturer in Sociology, Columbia Univ., and Lecturer in Anthropology, New School for Social Research

Harold Stevens, M.D., 3315–16th St., N.W., Washington 10, D. C., Consultant in Neuropsychiatry, Group Health Assn.

Ruth P. Stryker, R.N., 400 Holly Ave., St. Paul 2, Minn., Tuberculosis Field Nurse, State Dept. of Health

Emmy Sylvester, M.D., Ph.D., 55 E. Washington St., Chicago 2, Ill., Lecturer in Child Psychiatry, School of Social Service Administration, Univ. of Chicago

John B. Truslow, M.D., 630 West 168th St., New York 32, N. Y., Asst. Dean, Faculty of Medicine, Columbia Univ.

Virginia V. Vahey, M.S.S.W., 797 North Van Buren St., Milwaukee, Wis., Secy., Health Division, Community Welfare Council

Herbert G. Stoenner, D.V.M., Rocky Mountain Laboratory, U.S.P.H.S., Hamilton, Mont., Head, Veterinary Unit

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1949, the total membership of the Association was 11,102, including 2,093 Fellows, or almost 19 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine, with at least one year of graduate study in public health in a university, Master of Public Health, Diploma in Public Health, or other equivalent degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Applications are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that members themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although over 3,000 persons have been

duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health,* usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Committee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 13 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depend upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are $12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at $200, covering all future annual dues.

Applications for Fellowship to be considered at the 77th Annual Meeting in New York, N. Y., the week of October 24, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information, address the Membership Department, American Public Health Association.

A MESSAGE FROM THE CIRCULATION DEPARTMENT

Certain 1948 issues of the *American Journal of Public Health* are needed to complete sets for members and subscribers. The *Journals* that are in short supply are January, March, August, September, and October. It will be appreciated if members or subscribers who can spare any of these issues will mail them collect, addressed as follows: Circulation Department, American Public Health Association, 1790 Broadway, New York 19, N. Y.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

Sanitary Engineer — Well organized county health department. County is part of state student training area, generalized program. Total staff of 12 includes assistant sanitarian and sanitation clerk. County population 44,000, located on Lake Michigan, 140 miles from Chicago. Four weeks annual vacation. Salary range $3,600–4,500 plus travel, dependent on experience. Write: Arthur G. Baker, M.D. Director, Allegan County Health Dept., Allegan, Mich.

perience in medical and sanitary laboratory work; age 32; married; desires position in public health work. Write: Box L-6, Employment Service, A.P.H.A.

Public Health Physician, 39, M.D., M.P.H. from leading universities, considerable experience in local health administration and teaching in outstanding medical school and important public health responsibilities in the Army. Will consider desirable opening at salary consistent with background. Write: Box Ph-11, Employment Service, A.P.H.A.

Health Educator, female, 45, single, M.P.H. Considerable and responsible experience in local and national agencies and as executive secretary of health councils. Some teaching and editorial experience. Seeks challenging opportunity in a responsible position in official or voluntary health agency. Write Box HE-10, Employment Service, A.P.H.A.

Announcements

The U. S. Civil Service Commission announces an examination for Public Health Nurse, for positions in the U. S. Public Health Service and the Indian Service, throughout the country and in the Territories and possessions. Salaries range from $3,727 to $4,479 a year.

Applicants will be rated on the basis of education and experience. Requirements: a 3 year nursing course *or* a 2 year nursing course, plus appropriate nursing experience or education. Included in or supplementary to this education, applicants must show a minimum of 30 semester hours in an approved program of study in public health nursing and a minimum of one year's experience in public health nursing in a generalized community public health program. For positions paying $4,479, additional experience in staff nursing or supervisory experience is required. Current registration as professional nurses in a State, Territory, or the District of Columbia, at the time of appointment is required.

Maximum age limit for positions paying $3,727 in the Indian Service is 40 years; for all other positions to be filled, 62 years. Age limits are waived for persons entitled to veteran preference. Write: U. S. Civil Service Commission, Washington, D. C., or Civil Service regional offices. Closing date for applications is March 29, 1949.

Competitive examinations for appointment of Engineer Officers in the Regular Corps of the U. S. Public Health Service will be held on April 11, 12, and 13, 1949. Appointments will be made in the following grades:

1. Junior Assistant Sanitary Engineer (Second Lieutenant), entrance pay with dependents, $3,391.
2. Assistant Sanitary Engineer (First Lieutenant), $3,811.
3. Senior Assistant Sanitary Engineer (Captain), $4,489.

All grades are required to be U. S. citizens with a degree in one of the several branches of engineering from a school of recognized standing. (Undergraduate engineering students in the senior year are eligible to take the examination.) Additional requirements:

ASSISTANT GRADE:

Seven years of educational and professional training or experience subsequent to high school (including two years professional training or experience in a field of public health or related field).

SENIOR ASSISTANT GRADE:

Ten years of educational and professional training or experience after high school (including four years of professional training and experience in public health or related field).

Duty assignments include: sanitary engineering, water pollution control, industrial hygiene, malaria and typhus control, milk and food sanitation, and environmental health research activities.

Apply before March 18 to Surgeon General, U. S. Public Health Service, Washington 25, D. C., Division of Commissioned Officers.

New Continuous Examination Plan in New York State

Applications for oral examinations open to residents and non-residents of New York State are being continuously accepted for: Assistant District Health Officer and Senior Public Health Physician (Tuberculosis Control), beginning salary $6,154 with annual increments to $6,910; District Health Officer, $6,700 to $8,143; and Associate Public Health Physician (Tuberculosis

Control) and Associate Public Health Physician (Venereal Disease Control), $7,279 to $8,143.

Because of rapidly expanding programs and because there are more than twenty vacancies in higher paying positions in the state and local health departments, the opportunities for promotion will be unusually good after six months to one year of service. Other advantages are a month's vacation annually, liberal sick leave, and participation in the state retirement plan.

Qualifications for all positions include citizenship; graduation from an approved medical school; license or eligibility for license to practise medicine in New York State; one year's satisfactory internship or equivalent; successful completion of a postgraduate course in public health of one academic year in residence, approved by the New York State Public Health Council; and at least six months' satisfactory, full-time experience in a responsible public health position. Experience may be substituted for the postgraduate course in public health. Additional specialized experience is required for positions other than Assistant District Health Officer. Write: State Department of Health, Albany 1, N. Y., for details.

Fellowships Available in New York State Department of Health

Dr. Herman E. Hilleboe, New York State Commissioner of Health, announces the availability of Fellowships to train physicians to qualify for public health positions in New York State.

The Fellowship carries a stipend of $3,600 per year and is for one year or more, depending upon the training required. The content of the training is varied in accordance with the position for which the physician is being prepared. The types of training may be roughly grouped in four categories: Health Officer, TB Physician, Clinical Consultant, and Laboratory Director.

Further information and application forms may be obtained by writing to: Dr. Franklyn B. Amos, Director of the Office of Professional Training, New York State Health Department, Governor Alfred E. Smith State Office Building, Albany 1, N. Y.

Vacancies in New York City

The New York City Department of Health has six vacancies in the title of District Health Officer at the salary of $7,150 per annum. This position involves administrative responsibility for all activities of the Department of Health in a district with a population of approximately 250,000. Candidates must have an M.D. degree and one year of approved internship. In addition, they must have an M.P.H. degree and three years of experience as a health officer or assistant health officer or in another administrative public health position, or a satisfactory equivalent of this education and experience. Local legislation requires three years of residence in New York City immediately prior to appointment. This requirement will probably be waived in the case of outstanding applicants. Interested applicants are to write to the Bureau of Personnel of the New York City Dept. of Health, 125 Worth Street, New York 13, N. Y.

Opportunities in West Virginia, March, 1949

The following positions are now open in West Virginia:

Nutritionist I	$2,760–3,240
Nutritionist II	$2,520–3,000
Dental Clinician	$3,600–4,800
Dental Hygienist I	$2,400–2,880
Dental Hygienist II	$2,040–2,520

For further information write to: Mr. Paul B. Shanks, Administrative Assistant, State of West Virginia, Department of Health, Charleston 5, W. Va.

Nursing Education; seven years, teaching her specialty; four years, public health nursing administration; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

THE WORLD'S CHILDREN STILL NEED HELP

It will be remembered that the United Nations' Appeal for Children of 1948 had a goal of $60,000,000 to be raised in the United States. Although eminently successful in South Africa, Australia, New Zealand, Newfoundland, Canada, Iceland and the Scandinavian countries, the appeal failed lamentably in the United States, not more than half a million dollars having been raised for this country through private subscriptions for the United Nations International Children's Emergency Fund.

This Fund now announces that there is still opportunity for the people of the United States to share in the program by sending contributions directly to the Children's Emergency Fund, which is part of the United Nations.

Children's programs are being carried on in 13 European countries, China, 8 or 9 other countries in the Far East, and in Mexico. In Europe the program has up to the present been largely a feeding program but, with the abatement of the food crisis, is becoming more and more a medical program with chief emphasis upon tuberculosis control. In the Far East and Mexico, the program has been entirely medical, largely in the field of malaria and tuberculosis control.

Martha M. Eliot, M.D. traveled extensively in Europe in 1947 and 1948 as Chief Technical Consultant to the Children's Emergency Fund and still serves it in a consultant capacity. Henry F. Helmholz, M.D., of the Mayo Clinic has recently returned from Europe after a year's service as Chief Medical Consultant to the Fund.

Contributions to the child saving work of the Fund may be sent to the United Nations International Children's Emergency Fund, 405 E. 42nd St., New York.

DENTAL HEALTH BUREAU IN NEW YORK STATE

The New York State Department of Health recently moved to meet the increasing responsibilities of its expanded dental health program by giving its dental health section the status of a department bureau. The new program calls for intensification of the control of dental decay by all known methods. Special emphasis is being placed on the use of sodium fluoride on the teeth of children of school age or younger. The program also calls for more intensive postgraduate education for dentists in the diagnosis of cancer of the mouth since at least 10 per cent of all malignant cancers are found in and around the mouth, according to Herman E. Hilleboe, M.D., State Health Commissioner.

Other elements in the program are the correction of seriously crooked teeth and malformed jaws in children, especially when the defects are considered a handicap to the growth and development of the child, preventive orthodontics, and industrial dental hygiene.

David B. Ast, D.D.S., who has been director of the dental health section, Bureau of Maternal and Child Health, will head the new bureau.

66 HEALTH CENTERS APPROVED

By the end of October, 1948, a total of 540 project applications for federal grants under the Hospital Construction Act had been approved by the Surgeon General. More than 10 per cent of these, 66 in number, were health centers and 3 were health department laboratories.

ROBERT GOULD RESEARCH FOUNDATION GRANT TO JOHNS HOPKINS

Dr. Detlev W. Bronk, newly installed President of Johns Hopkins University, Baltimore, has announced that the Robert Gould Research Foundation, Cincinnati, has made a grant of $5,000 for research in 1949 by Professor E. V. McCollum, Professor Emeritus of Biochemistry at the School of Hygiene and Public Health. The grant is intended to assist Dr. McCollum to continue his experiments in the chemistry of nutrition, particularly the separation in pure form of amino acids.

The Robert Gould Research Foundation is devoted primarily to the advancement of the science of nutrition. Other recipients of grants-in-aid from the Foundation are Cornell University, Ohio State University, University of Toronto, the University of Wisconsin, the National Research Council and the University of Cincinnati to which the Foundation has given a comprehensive library on nutrition.

HERMANN M. BIGGS MEMORIAL LECTURE

Howard A. Rusk, M.D., professor and chairman, department of rehabilitation and physical medicine, New York University College of Medicine, and Associate Editor, *The New York Times*, will deliver the annual Hermann M. Biggs Memorial Lecture of The New York Academy of Medicine at the Academy's Hosack Hall on April 7, 8:30 P. M. The subject of the lecture will be "The Medical, Social, and Public Health Aspects of Rehabilitation," and is open to the general public.

DR. JOHN WHITNEY LEAVES NEW ORLEANS FOR AMERICAN RED CROSS

The resignation of John M. Whitney, M.D., as City Health Superintendent of New Orleans, effective February 1, was recently announced. Dr. Whitney is a graduate of the Tulane University Medical School and was appointed Superintendent of Health in March, 1941. According to the announcement, his new position will be that of Medical Director for the Eastern Division of the American National Red Cross.

Dr. Whitney served for some years as Secretary of the Southern Branch, American Public Health Association, and the 1948 meeting of the Branch was held under very favorable auspices in New Orleans.

WISCONSIN PUBLIC HEALTH CONFERENCE

The Wisconsin Public Health Conference of December 20 and 21, arranged by the State Public Health Council and sponsored jointly with the State Board of Health, the Wisconsin Public Health Association, and the University of Wisconsin, addressed itself to making the state's citizens community public health conscious. The first day was devoted to the problem of local health units, their development through local health councils, their functions, and their administrative organization. These subjects were dealt with by a panel made up of Drs. John W. Ferree, Roscoe P. Kandle, Vlado A. Getting, and Haven Emerson.

The second day was devoted to the more detailed discussion of specialized activities of a local health department—sanitation, laboratory, mental hygiene, public health nursing, dentistry, and hospital and health department coördination—with a panel of six including Ellis S. Tisdale, Margaret Taylor, and Drs. G. D. Cummings, Frederick S. McKay, Paul H. Stevenson, and Basil McLean.

The Wisconsin Public Health Association was fully organized at this meeting with a constitution and by-laws designed to make it eligible for affiliation with the A.P.H.A.

PUBLIC HEALTH PRACTICES INSTITUTE FOR VETERINARIANS

To give the veterinarian better understanding of public health objectives and

practices, the Illinois Department of Public Health is sponsoring an Institute on Public Health Practices for Veterinarians to be held in Springfield, Ill., March 21–March 23, 1949, to which all veterinarians are invited. The program has been designed better to acquaint veterinarians with the three basic public health practices, namely, epidemiology (disease reporting), public health education, and disease prevention and control. Participants in the program have been selected from both veterinary and public health fields upon a basis of their experience and qualifications in these fields.

Though not specifically stated, this Institute is presumably open without fees to veterinarians both in Illinois and outside the state. Hotel accommodations are being handled by the Secretary of the Convention Department, Springfield Chamber of Commerce, Springfield, Ill.

NORTH CAROLINA SUMMER INSTITUTE OF STATISTICS

The Institute of Statistics of the University of North Carolina announces a summer session, June 9–July 19, 1949, at Chapel Hill. Intensive instruction will be offered for the benefit of:

1. Research scholars in other sciences who want a practical working knowledge of statistical theory
2. Statistical consultants in various fields
3. Those preparing to teach statistics or to develop statistical theory
4. Students working toward a degree in applied or theoretical statistics

Several applied courses will deal with statistical analysis and designs for research work in medicine, public health, and nutrition.

Among the staff are the following:

G. W. Snedecor, Director of the Statistical Laboratory, Iowa State College and author of the textbook, *Statistical Methods*

D. J. Finney, lecturer in the design and analysis of scientific experiment, University of Oxford, England

J. Wolfowitz, Associate Professor, Department of Mathematical Statistics, Columbia University

R. C. Bose, recently professor, Calcutta University, India

Futher information from Gertrude M. Cox, Director, Institute of Statistics, the University of North Carolina, Box 168, Chapel Hill, N. C.

RICHLAND COUNTY HEALTH NEWS

December, 1948, saw the first issue of *Your Health,* sired jointly by the Mansfield-Richland County (Ohio) Health Department, the County Tuberculosis Association, and the Mansfield unit of the American Cancer Society. Starting with the maxim "Health begins with education," its aim is to make general knowledge in its community of 75,000 what is at present known about health to only a few, and thus increase the average expectation of life about ten years. Richland County Health Department, Mansfield, Ohio.

PHILADELPHIA HEALTH SURVEY

A city-wide health survey of Philadelphia is being conducted by the Health and Welfare Council under the general supervision of an executive committee appointed by the Council, the City Planning Commission, and the Philadelphia Department of Public Health. The survey will be made jointly by Roscoe P. Kandle, M.D., and Carl E. Buck, Dr.P.H., Field Director and former Field Director respectively, of the American Public Health Association. Among other uses the study will serve as a basis for planning the health center administration of the city health department.

DR. DONALD DUKELOW APPOINTED A.M.A. BUREAU CONSULTANT

The appointment of Donald A. Dukelow, M.D., of Minneapolis as Medical Consultant in Health and Fitness of the American Medical Association Bureau of Health Education, Chicago, was re-

cently announced. Dr. Dukelow has been Director of the Committee on Medical Care of the Community Chest and Council of Hennepin County, Minnesota. He is the Secretary of the Health Education Section of the A.P.H.A. The appointment will become effective March 1.

HEALTH INSURANCE BILLS INTRODUCED INTO 81ST CONGRESS

Bills identical with S 1320—the Murray-Wagner-Dingell bill for compulsory health insurance of the 80th Congress—were introduced into both House and Senate in the opening days of the 81st Congress. The Senate bill, introduced by Senators Murray, Wagner, and McGrath is numbered S 5. The House bills, HR 345 and HR 783, were introduced respectively by Representative Celler and referred to the House Ways and Means Committee, and by Representative Dingell and referred to the Committee on Interstate and Foreign Commerce.

FILM CATALOG-UTILIZATION GUIDE

The Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga., has prepared a looseleaf guide describing the films and film strips that have been prepared by the Service. The *Guide* is divided into sections, depending upon the subject matter. Each film or film strip is described on a separate sheet, with blank space for the user to make comments concerning its applicability and value. It is not anticipated that everyone using films would have need for the entire *Guide*. On the contrary, it is anticipated that each person will request the portion of the *Guide* of particular interest to him. The *Guide* is classified in the following headings: Anatomy and Physiology, Entomology, Hospitals, Insect Vector Control, Laboratory Techniques, Parasitology, Quarantine, Rat Borne Disease Control, Sanitation and Sanitary Engineering, Tropical Diseases and Infectious Diseases, Venereal Disease Control, Veterinary Medicine and Activities, and Visual-Aids Techniques.

LIFSON TO HEART ASSOCIATION

Sol S. Lifson is the latest addition to the staff of the American Heart Association in its program of expanding service and developing local heart associations. As supervisor of field services of the public health division, he will be responsible for the program development and community organization field services of the association.

In this capacity he will be working in the same relationship to John W. Ferree, M.D., the director of the division, that he has occupied for the last year and a half in the National Health Council. Both men were formerly on the staff of the Council, Dr. Ferree having gone to the heart association on January 15, Mr. Lifson on March 1.

Before coming to the National Health Council, Mr. Lifson was for four years health education consultant in the U. S. Public Health Service, and has had health education teaching experience in the Massachusetts Institute of Technology, New York University, and Yale University where he is currently lecturer in public health with the rank of assistant professor. He is Secretary of the School Health Section of the American Public Health Association and member of the executive committee, National Publicity Council.

AMA'S PR DOCTOR

In August, 1948, the American Medical Association issued the first of its "The PR Doctor Series." This is a bi-monthly four-page public relations news letter designed "to encourage the development and conducting of public relations projects by state societies, and their coöperation toward common public relations goals." As such it gives a round-up of current trends, activities,

and opinion on medical public relations topics.

PR Doctor is distributed to trustees, officers, and members of the House of Delegates of A.M.A. and to officers, journal editors, and public relations committees of state societies. It is prepared in the office of the executive assistant for coördination and public relations, Lawrence W. Rember, 535 N. Dearborn St., Chicago 10.

DR. KOGEL, NEW YORK CITY HOSPITAL COMMISSIONER

On February 1, Marcus D. Kogel, M.D., became New York City Commissioner of Hospitals, succeeding Edward D. Bernecker, M.D., resigned. As such, he will have charge of the city's 28 municipal hospitals with a total bed capacity of more than 20,000, and a patient census of three per cent above capacity on the day he took office. The annual departmental budget is nearly $70 million.

Except for two periods of service in the Army Medical Corps, Dr. Kogel has been in the Department of Hospitals since it became a separate department exactly 20 years before he took office as Commissioner. He started as Deputy Medical Superintendent of Cumberland Hospital, then became Medical Superintendent of Queens General Hospital, and for the past two years has been General Medical Superintendent of the Hospital Department. During the recent war he was chief of preventive medicine of the China Theater and was awarded the Legion of Merit for his services while in that assignment. He is a Fellow of the American Public Health Association.

Among the new projects announced for the department by Commissioner Kogel are: the extension of home care service to relieve the shortage of hospital beds, reorganization of clinic services, breaking the "bottleneck" of x-ray and laboratory services which now contributes to bed shortages, and an experimental program to relieve the nurse shortage.

SAFE DISPOSAL OF RADIOACTIVE WASTES

In January the Atomic Energy Commission sponsored a two day seminar in Washington, D. C., on disposal of radioactive wastes, to which were invited water works and sanitary engineers, both from private industry and from state and federal government departments. In addition to scientists from the federal atomic energy projects, Abel Wolman, Dr. Eng., head of sanitary engineering at Johns Hopkins University, was among the speakers. The conclusions in part are: "So far as external ionizing radiation is concerned, there is no hazard with proper methods of disposal. From the standpoint of internal radiation, to the best of our knowledge, the precautions we are utilizing are giving adequate protection."

FOOD INSPECTORS' AND SANITARIANS' SHORT COURSE

The 6th annual Dairy and Food Inspectors' and Sanitarians' School will be held at Michigan State College on April 4–7 for the busy worker in these fields to secure the latest information on many aspects of food inspection with a minimum of time and expense. Details of the school and a copy of the program may be obtained from Dr. W. L. Mallmann, Department of Bacteriology and Public Health, Michigan State College, East Lansing.

DR. RINGLE RESIGNS AS STATE HEALTH OFFICER

Arthur M. Ringle, M.D., resigned as Director of the Washington State Department of Health as of December 1 to assume a medical administrative post with the Branch office of the Veterans' Administration in Seattle.

Dr. Ringle has served as Director since January 22, 1945, having formerly

been Health Officer of the Walla Walla-Benton-Franklin District.

During Dr. Ringle's administration four new programs were added to the State Department's work, including cancer control, mental hygiene, hospital planning, and conservation of hearing. Dr. Ringle is the President-Elect of the Western Branch A.P.H.A., and special consultant to the Mental Hygiene Division, U. S. Public Health Service.

The administrative duties of the department have been assumed temporarily by J. A. Kahl, M.D., Assistant Director, until a successor is appointed.

BILLS IN HOUSE FOR WELFARE CABINET POST

Representatives Harris and Dawson have introduced into the 81st Congress HR 184 and HR 782, providing for departmental status and thus cabinet rank for its administrator for the Federal Security Agency. The bills will be considered by the House Executive Expenditures Committee of which Congressman Dawson is chairman.

ROYAL SANITARY INSTITUTE MEETING TO BE HELD IN BRIGHTON

It has been announced from England that the meeting of the Royal Sanitary Institute will be held in Brighton, May 23–27.

It is requested that Fellows and members of the American Public Health Association who expect to be in Great Britain during May will communicate with the Executive Secretary.

WASHINGTON LOCAL HEALTH OFFICERS RECOMMEND LEGISLATION

The Washington State Local Health Officers Association at its annual meeting late in 1948 recommended the following measures for consideration by the state legislature:

1. Reorganization of the State Board of Health to have legal authority for all state-wide public health measures and to consist of 9 members appointed for 6 year terms by the Governor with Senate approval. One would come from each Congressional district, plus 3 members at large. The board now has 5 members, appointed and serving at the pleasure of the governor.

The new board would be empowered to select the State Director of Health for a 6 year term. At present he is appointed by and serves at the pleasure of the governor. Under the proposed legislation, he must be a qualified physician with postgraduate training in public health and 5 years' experience in public health administration. His salary would be fixed by the Board. At present a physician is specified, but no public health experience is required.

2. Legislation enabling cities of more than 100,000 population to combine into city-county health departments.

3. The health officers ask that the 3 cents per capita now contributed by the state to local full-time health departments be raised to 30 cents, and that a total of $625,000 a year be made available for subsidy to full- and part-time health departments.

1949 OFFICERS OF MUNICIPAL PUBLIC HEALTH ENGINEERS

At the recent meeting of the Conference of Municipal Public Health Engineers in Boston, at the time of the A.P.H.A. annual meeting, the following officers and Executive Committee were elected:

Chairman—Morton Hilbert
Vice Chairman—Herbert Dunsmore
Secretary-Treasurer—Arthur H. Herberger
Executive Committee—
William H. Cary—1949
William J. Dixon—1949
William R. Hardy—1950
Henry D. Peters—1950
Joel C. Beall— 1951
Charles L. Senn—1951

The Conference adopted a resolution recognizing the value of the Engineering Section Project of A.P.H.A. and requesting the Executive Board to continue it.

RUSSIA INDICATES WITHDRAWAL FROM WHO

It was announced in Geneva on February 16 by the World Health Organization that the Soviet Union, together with the Ukraine and Byelorussia, have notified WHO that they no longer consider themselves members of WHO.

According to Dr. Brock Chisholm, Director General of WHO, the withdrawal of the Soviet Union from the only specialized agency of the United Nations to which it belonged came without warning. The Soviet Union's reason was given as failure of WHO to carry out the tasks set forth by the World Health Conference of 1946. Moscow was quoted as saying "The tasks connected with international measures for the prevention and control of diseases and with the spread of the achievements of medical science are not being accomplished." Also, "At the same time, maintenance of the organization's swollen administrative machinery involves expenses which are too heavy for member states to bear."

Dr. Chisholm pointed out in his reply that the constitution of the organization contains no provision for the withdrawal or the expelling of a member. The United Nations had decided that membership in WHO should be permanent and unretractable. He urged that other governments attempt to persuade Russia to reconsider inasmuch as the organization had been in full operation only four and a half months. The organization is short of money and is newly acquiring staff. It was stated that the Soviet Union, the Ukraine and Byelorussia have made no payment on their contributions which total to date $350,000. Dr. Chisholm said that WHO had repeatedly asked the Soviet Union for experts to act on its technical committees and it was said by a WHO spokesman that Russia had worked side by side with other members of WHO in trying to halt the outbreak of cholera in Egypt, the increase of tuberculosis in Central Europe, and malaria epidemics in Greece, Yugoslavia, and other countries.

AMERICAN BOARD OF PREVENTIVE MEDICINE AND PUBLIC HEALTH NOW IN OPERATION

Readers of the *American Journal of Public Health* have been advised of the incorporation of the American Board of Preventive Medicine and Public Health on June 29, 1948, and the organization of the Board of Trustees of the corporation with representatives from the American Medical Association, the American Public Health Association, the Canadian Public Health Association, the Association of Schools of Public Health, and the Southern Medical Association.

According to an announcement by Ernest L. Stebbins, M.D., of Baltimore, Secretary of the Board, the applications of the American Board of Preventive Medicine and Public Health, Inc., for approval by the Advisory Council on Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association were approved in early February. Dr. Stebbins has indicated that the Board is now officially in operation and that it is prepared to receive applications from physicians wishing to have their specialty qualifications in preventive medicine and public health certified. Correspondence should be directed to Dr. Stebbins at 615 N. Wolfe Street, Baltimore, Md.

In addition to the Trustees of the Board whose names have already been published (*A.J.P.H.*, Vol. 38, No. 9, September 1948, page 1348; November 1948, page 1619), three newly elected Trustees at large attended the meeting held in Chicago in February. These *included:*

Gaylord W. Anderson, M.D., Minneapolis, Minn., M. R. Kinde, M.D., Battle Creek, Mich., and Emil Palmquist, M.D., Seattle, Wash.

As already announced, it is anticipated that the Interim Board on Preventive Medicine and Public Health, which was created by the Surgeons General of the U. S. Public Health Service, U. S. Air Corps, U. S. Army, and U. S. Navy, for the certification of medical specialists in public health and preventive medicine from the Government Services, will be terminated in view of the organization of the American Board of Preventive Medicine and Public Health, Inc. In view of the approval of the latter by the action already noted it was expected that 315 applications for certification from the Services which are now in the hands of the Interim Board would be transferred to the American Board of Preventive Medicine and Public Health for review.

It is anticipated that the new Specialty Board will hold its first examination in Washington, D. C., on May 15 and 16, 1949, and that the next examinations will be held in New York City preceding the 77th Annual Meeting of the American Public Health Association on October 22 and 23. Applications are said to close 60 days before the announced dates.

The *American Journal of Public Health* will carry in a forthcoming issue a digest of the conditions to be met by those who are certified by the Board.

DR. ROSEN DIRECTOR OF BUREAU

George Rosen, M.D., Ph.D., has been named director of the Bureau of Health Education of the New York City Health Department, succeeding Israel Weinstein, M.D., now on terminal leave. Except for a three year period on military leave, Dr. Rosen has been with the department since 1941, first as clinic physician in the Bureau of Tuberculosis and, since 1946, as district health officer. He edits a column "Public Health in Foreign Periodicals" in the *American Journal of Public Health* and is a member of the Editorial Board.

NEW HAMPSHIRE MEDICAL SOCIETY APPROVES STATE PROVIDED LOCAL HEALTH SERVICES

A constant reader and contributor sends the following to News from the Field, taken from the Proceedings of House of Delegates, New Hampshire Medical Society, June, 1948, reported in the *New England Journal of Medicine:*

State legislative support for more adequate local health services in New Hampshire will be sought by the state medical society, according to action taken by the House of Delegates in June, 1948, on a report of its Committee on Public Health. The report pointed out that local services could best be provided by a series of district offices staffed by full-time workers from the State Department of Health. A demonstration in Exeter for the past six years proved the value of regionalization of state services. Development of direct services from local units or from county units was deemed undesirable because of financial and personnel shortages for a multiplicity of small part-time units. The new dental program of the state health department was cited as a successful device for bringing specialized services to the public.

DR. MELENEY TO STUDY PUBLIC HEALTH IN NEAR EAST

Henry E. Meleney, M.D., Hermann M. Biggs Professor of Preventive Medicine, New York University-Bellevue Medical Center, New York City, left New York on February 8 for Beirut, Lebanon, where during a six months sabbatical leave he will make a study of public health teaching needs at the American University.

Dr. Meleney's study under a grant from the Commonwealth Fund will form the basis of a future program to meet the needs for the development of public health personnel to promote and maintain the health of industrial populations as well as for general improvement in public health.

BIBLIOGRAPHY ON PLUMBING AND PUBLIC HEALTH

The U. S. Public Health Service has recently made available a revised bibli-

ography on "Plumbing and Public Health." It includes items up to July 1, 1948, and replaces the previous bibliography published in 1940. Five hundred thirty-one references are contained in the bibliography. Copies may be obtained from the U. S. Public Health Service, Division of Sanitation, Washington, D. C.

CORRECTION

The January, 1949, issue of the *American Journal of Public Health,* page 6, among the High Points of the Boston meeting, quotes Mr. J. J. Bloomfield on Shaver's Disease, which it states was first reported in Kansas by Dr. Shaver.

Through a stenotypist's error this should have indicated that Dr. Shaver first reported the disease in Canada.

PERSONALS

DEWITT S. ABELL † is now associate chief of party and chief engineer, health and sanitation division, Institute of Inter-American Affairs, after serving as chief sanitary engineer, UNRRA in China. He can be addressed c/o American Embassy, Montevideo, Uruguay.

LOUISE AGNEW, R.N., was named to the Lawton-Comanche County (Oklahoma) Health Department, early in December. KENNETH C. KIDD, was appointed Sanitarian of the same county.

F. KENNETH ALBRECHT, M.D.,† formerly of the U. S. Public Health Service and more recently medical editor for The Williams & Wilkins Company, Baltimore, Md., has been appointed Director of the Division of Tuberculosis Control, Kansas State Department of Health.

EDWARD M. BERNECKER, M.D., has resigned as New York City Commissioner of Hospitals to become Administrator of Hospital Services for the New York University-Bellevue Medical Center. In the City Hospital Department since 1920, Dr. Bernecker had been Hospital Commissioner since 1942.

CARROLL S. BRINSFIELD has been appointed Maryland State Food and Drug Commissioner, to succeed the late A. L. SULLIVAN.

ROWLAND BURNSTAN, who has served for 2 years as Executive Director of the New York State Charities Aid Association, New York City, has resigned to enter private business.

HELEN CANNON † has been appointed director of the section on Social Services of the Preventive Medicine Division of the Colorado State Department of Public Health. This section has been developed to provide generalized social service consultants to the several geographical areas of the state.

ALTA ELIZABETH DINES * retired on December 31 as Director of the Department of Educational Nursing of the Community Service Society of New York after serving the agency for 25 years. She is a member of the nursing scholarship committee of the National Organization for Public Health Nursing and of the Isabel Hampton Robb Memorial Fund which provides scholarships for nurses for advanced study, and is 1st vice-president of the Harmon Association for the Advancement of Nursing.

VIVIAN V. DRENCKHAHN, M.P.H.,* has been appointed Director of the Health Education Service of the National Tuberculosis Association, New York, on which staff she has served for 3 years.

DAVID R. L. DUNCAN, M.D.,† formerly a school physician of the Denver public schools, began his duties as Health Officer for the Las Animas-Huerfano (Colorado) Health Department on January 1.

GEOFFREY EDSALL, M.D.,* Director of the Division of Biologic Laboratories of the Massachusetts State Depart-

ment of Health, has taken over the editorship of the Journal of Immunology, the only such technical publication specializing in this field in the English language.

PROFESSOR GORDON M. FAIR,* Dean of the Graduate School of Engineering and Gordon McKay Professor of Sanitary Engineering at Harvard University, has been appointed Master of Dunster House, Cambridge, Mass., where he has taken up residence with the 371 students and 12 staff members.

GEORGE E. FARRAR, JR., M.D., Associate Professor of Medicine at Temple University, Philadelphia, Pa., has been appointed Medical Director for Wyeth, Inc., in the same city, to advise the management on medical affairs. He will continue his post at Temple University as co-author of the U. S. Dispensatory.

LLOYD J. FLORIO, M.D., Dr.P.H.,* has been promoted to Professor and Head of the Department of Preventive Medicine and Public Health, recently established at the University of Colorado Medical School, Denver. Dr. Florio has recently been on loan to the Denver Department of Health as Health Officer, pending the appointment of JAMES P. DIXON, JR., M.D.†

LUKE W. FRAME, M.D., Director, Bureau of Communicable Disease Control, West Virginia State Health Department resigned November 30 to assume directorship of the newly created Huntington-Cabell Health Department.

LLOYD H. GASTON, M.D., Dr.P.H.,† has been appointed Director of St. Luke's Hospital, New York City, effective January 1. He has been Acting Director since the retirement on July 1, because of ill health, of CLAUDE W. MUNGER, M.D.

AGNES E. GERDING, R.N.,† who has served as Executive Secretary of the Suffolk County Tuberculosis and Health Association, Long Island, N. Y., has resigned to become an Associate in Program Development for the National Tuberculosis Association, New York City.

LOWELL S. GOIN, M.D., of Los Angeles and J. ELLIOTT SCARBOROUGH, JR., M.D., of Atlanta were recently appointed to the National Advisory Cancer Council by LEONARD A. SCHEELE,* Surgeon General of the U. S. Public Health Service.

MANUEL GONZALEZ-RIVERA, M.D.,† who has been working in the Institute of Public Health and Tropical Diseases and in the School of Public Health, Mexico City, has been appointed Director of the National Health Museum, Mexico City.

WILLIAM S. GROOM,† for 8 years President of the Public Health Federation of Cincinnati and for the past 4 years its volunteer Director of Health Education, has received the Award of Honor for 1948 for distinguished service to the cause of public health in Greater Cincinnati.

KENNETH W. HAWORTH, M.D.,† formerly Health Officer of the Humboldt County Health Department, has become the first full-time Health Officer of Napa County, California.

MURIEL CROTHERS HENRY, has been appointed to handle public relations for the Committee on Careers in Nursing, sponsored by the six national nursing organizations. Mrs. Henry was most recently Director of Public Relations for the Chicago Travelers Aid Society.

R. L. HOWELL has been named Sanitarian for District 1 Health Department, made up of 5 Oklahoma Counties with headquarters in Wagoner.

CECIL G. HUPP, M.D., has succeeded W. B. JOHNSON, M.D.,* as Maryland Deputy State Health Officer in Caroline County.

---

* Fellow A.P.H.A.
† Member A.P.H.A.

WILLIAM H. IRELAND has been appointed Executive Secretary of the Council of Social Agencies, Akron, Ohio. Since 1946 he has been head of neighborhood services of the council.

NORMAN JOLLIFFE, M.D.,* has been appointed head of the New York City Department of Health's newly organized Bureau of Nutrition under a plan to open five additional clinics throughout the city in 1949.

HILDA H. KROEGER, M.D.,* Director of Maternal and Child Health, Arizona State Department of Health (Phoenix), has been appointed Assistant Director of Grace-New Haven Community Hospital, Conn., and Professor of Hospital Administration at Yale University.

CHARLES MACNAMARA has been named Executive Secretary of the Lake County (Illinois) Tuberculosis Association, succeeding ORPHA WHITE, deceased.

HARRIETTE M. MALONE has joined the staff of the Social Hygiene Committee, New York Tuberculosis and Health Association.

D. FRANK MILAM, M.D.,* for the past 25 years a member of the Field Medical Staff of the International Health Division of the Rockefeller Foundation, has been named National Director of the Planned Parenthood Federation of America with headquarters in New York.

ALBERTA M. MORGAN, R.N.,† is the new Nursing Consultant in Maternal and Child Health of the Public Health Nursing Division, Arizona State Health Department, Phoenix.

JAKE MILLER, KEITH HANGER and R. S. JACOBSON have recently completed training as sanitarians at the West Virginia Public Health Training Center, Morgantown, W. Va. Messrs. Miller and Hanger have now been assigned to Kanawha County and Mr. Jacobson has been assigned to District No. 1, with an office at Summersville.

RUSTIN MCINTOSH, M.D., Carpentier Professor of Pediatrics, College of Physicians and Surgeons of Columbia University and Director of the Pediatric Service, Presbyterian Hospital, New York, has been elected 1949 Chairman of the American Council on Rheumatic Fever of the American Heart Association, succeeding H. M. MARVIN, M.D. LAWRENCE LINCK,† Executive Secretary of the National Society for Crippled Children and Adults, was elected Vice Chairman.

JOHN W. R. NORTON, M.D.,* Raleigh, N. C., State Health Officer, received the first Reynolds Medal and scroll at the October, 1948, meeting of the North Carolina Public Health Association in Durham. Given in honor of former State Health Officer, CAROL V. REYNOLDS, M.D.,* the medal is awarded to the association member who presents the most outstanding address or paper at the convention.

SIR JOHN BOYD ORR, M.D.* former head of the United Nations Food and Agricultural Organization, was made a Baron according to the New Year Honors List published on behalf of King George VI of Great Britain. Sir John is an Honorary Fellow of the A.P.H.A.

SAMUEL B. OSGOOD, M.D.,* is now epidemiologist and director of the venereal disease control section of the Oregon State Board of Health (Portland). He has served as Josephine County Health Officer for the past 12 years.

W. PHILLIPS PALMER,† Consultant in Hospitals and Medical Care, West Virginia State Health Department, resigned on November 15 to join the Medical staff of the United Mine Workers Health and Welfare Fund area program in Pittsburgh, Pa.

JEROME S. PETERSON, M.D., M.P.H.,* who has been Acting Professor of Pre-

ventive Medicine and Community Health at the Long Island College of Medicine, Brooklyn, N. Y., for several months, has left for Palestine to serve with the American Friends Service Committee in the southern Palestine area near Gaza in care of refugees. Dr. Peterson is on leave from WHO for a period of 8 months for this project which is under the auspices of the United Nations.

JOHN J. PHAIR, M.D., Dr.P.H.,* who has served as Director of Health of the Louisville and Jefferson County Board of Health, (Ky.) for some years, has accepted the position as Professor of Preventive Medicine at the School of Medicine, University of Cincinnati, effective July 1, 1949. In the meantime he is serving as Acting Professor.

ADELAIDE R. ROSS,* formerly director of the department of adult health education, District of Columbia Tuberculosis Association, on February 7 became Assistant Professor of Health Education at the University of Maryland, College Park.

MAJOR ARVEY C. SANDERS,† of Crosby, Minn., is currently assigned to the Bacteriology Section of the 406th Medical General Laboratory in Tokyo, Japan, seat of the headquarters of General of the Army Douglas A. MacArthur.

DEAN THORNDIKE SAVILLE,* of New York University College of Engineering, has been appointed sanitary engineering member of the National Advisory Health Council, U. S. Public Health Service. Dean Saville has been head of the College of Engineering since 1936. He is a member of the New York State Public Health Council.

CLARENCE L. SCAMMAN, M.D.,* who recently retired as Director of the Division of Public Health, The Commonwealth Fund, New York City, has been appointed Medical Director of the Massachusetts Division, American Cancer Society, Boston, effective January 3.

DONAL SHEEHAN, M.D., formerly Director of the Commonwealth Fund, has been appointed Chairman of the Scientific Committee, New York University-Bellevue Medical Center, and Professor and Chairman of the Department of Anatomy at the New York University College of Medicine, New York City, where he will direct the overall program of teaching and research to be carried out at the center.

GLADYS SMITH, M.D., has been appointed Assistant Health Officer for the Pottawatomie County Health Department, Oklahoma.

MARY STEICHEN, M.D., M.P.H.,* of Great Neck, Long Island, N. Y., has been appointed school physician of the Great Neck public schools.

R. J. VAN DERWERKER,† Senior Sanitary Engineer, has been assigned by the U. S. Public Health Service to the Pan American Sanitary Bureau, Washington, D. C., as Chief Sanitary Engineer, succeeding DONALD L. SNOW,† who has been transferred to the National Institutes of Health.

JAMES WATT, M.D.,* of the staff of the U. S. Public Health Service, directs the Diarrheal Disease Investigations Laboratory located at the Medical School of Louisiana State University, New Orleans, where studies are under way among new-born infants. Dr. Watt serves as clinical professor of preventive medicine at Louisiana State University.

GEORGE M. WHEATLEY, M.D.,* formerly Assistant Vice-President of the Metropolitan Life Insurance Company, has been promoted to Third Vice-President and will continue in Association with DONALD B. ARMSTRONG, M.D.,* Second Vice-Presi-

* Fellow A.P.H.A.
† Member A.P.H.A.

dent in charge of the Health and Welfare Division, New York.

SAMUEL M. WISHIK, M.D.,* former assistant director of the Division of Health Services of the U. S. Children's Bureau in Washington, D. C., has been named head of the New York City Health Department's recently reorganized Bureau for Mothers and Young Children.

TOM P. WUICHET, M.B.A., who recently received his degree from Ohio State University, has joined the staff of the Ohio State Department of Health, Columbus, as Personnel Officer.

MARJORIE A. C. YOUNG, M.P.H.,† has been appointed Consultant in Education of the National Society for the Prevention of Blindness, New York. Miss Young has been Associate Professor of Health Education for the past 2 years at Springfield College, Springfield, Mass.

JOHN W. YOST, M.D., was appointed full-time Director of the Bluefield City (West Virginia) Health Department, on November 1, 1948. Dr. Yost, a practising physician and part-time Health Officer of Princeton, succeeds RICHARD C. NEIL, M.D., who served on a part-time basis since the death of D. B. LEPPER, M.D.

Deaths

ROSE K. BUTLER, R.N.,† Executive Director, Visiting Nurse Association, Holyoke, Mass. (Public Health Nursing Section).

CECIL K. CALVERT,* Superintendent of Purification Department, Indianapolis Water Co. (Engineering Section).

ARTHUR T. DAVIS, Health Commissioner of Suffolk County, New York, since the county's health department was formed in 1929, died December 17.

DANIEL W. MEAD,* of Mead and Hunt, Consulting Engineers in Madison, Wis., died October 13, 1948 (Engineering Section).

MICHAEL J. NESTOR, M.D., City Registrar and Superintendent of the Providence (Rhode Island) Health Department from 1935 until he resigned in November, died January 9 at the age of 72.

THE NINTH EDITION

of

STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS

is now available

This manual, prepared by the Committee on Examination of Milk and Milk Products, outlines procedures for the routine microbiological and chemical examinations of the more common dairy products used as food. It includes directions for enumerating, isolating, and identifying members of the coliform group, *Brucella,* streptococci, tubercle bacilli, *Salmonella,* pathogenic *Shigella,* and enterotoxigenic staphylococci.

The resazurin reduction method for the examination of fluid milk is included in this edition. Procedures are given for the examination of condensed milk, dried milk, evaporated milk and of fruits, nuts, flavoring and coloring materials, eggs and egg products, sweetening ingredients and stabilizers when used as ingredients in frozen desserts.

The primary aim in the new edition is to aid the laboratory worker by maintaining uniformity of arrangement and style, by using a system of simple cross references, and by improving the index. To do this, the first chapter on "Selection and Interpretation of Quality Tests" is organized for the guidance of the administrator. The succeeding twelve chapters, now relatively free from interpretive and explanatory matter, provide tried and tested methods for the laboratory worker. A group of "Screening Tests," which do not have approval for unqualified use, but which permit more frequent examinations than otherwise could be made, appear in the last chapter.

The thirteen chapter headings are listed below.

1. Selection and Interpretation of Quality Tests
2. Microbiological Methods for Milk and Cream
3. Detection of Special Bacterial Groups or Species
4. Microbiological Methods for Butter
5. Microbiological Methods for Cheese
6. Microbiological Methods for Frozen Dessert Ingredients
7. Microbiological Methods for Frozen Desserts
8. Sterility Tests for Dairy Equipment
9. Tests for Sediment and Extraneous Matter in Dairy Products
10. Determination of Vitamins
11. Phosphatase Methods to Determine Pasteurization
12. Chemical Methods
13. Screening Tests

When you work with live animals, you can eliminate one big variable by feeding uniform Purina Laboratory Chow. Here's a ration made with a formula as standard as lab equipment, as constant as the best lab techniques, bag after bag, everywhere across the nation. That's why more and more research workers are standardizing on Purina Laboratory Chow. They can depend on it from year to year on their own projects, and they can rely on comparisons with other research scientists who use it on similar problems throughout the country. Try Purina Laboratory Chow...a standard you can count on.

C-O-M-F-O-R-T YOU HAVE NEVER KNOWN BEFORE

"WASHED" AIR IS WHOLESOME AIR

The moment you enter a Rexaired room, you will notice how fresh the air is; how comfortable it is to breathe. Rexair is the amazing new appliance that actually improves the air you breathe.

Rexair takes dust from carpets, bare floors, drapes, upholstered furniture, and from the air itself. Rexair collects dust and dirt in a water bath; discharges cleaner and moistened air back into the room.

The longer Rexair runs, the cleaner and fresher the air becomes. Rexair has no porous bag from which dust can escape back into the air you breathe. Dust is permanently trapped in water. You pour the water down the drain—dust and dirt go with it.

Illustrated at the right is a Rexair with the reservoir cut away to show the water which traps and holds dust so that it cannot escape. You feel better and work better when the air you breathe is clean, fresh, and wholesome.

Spring 1949

With the approach of Spring, our thoughts turn to spring clothes. For the Public Health Nurse, a beautiful Smith-Gray Princess style double-breasted or a Box style single-breasted topcoat, of gabardine or whipcord, will provide style, comfort, and that essential Spring Look. Your SMITH-GRAY water repellent topcoat can be made an All-Season coat, if you wish. A tailored zip-in removable lining converts a topcoat to an all-purpose coat—topcoat—overcoat—raincoat. Zip-in the lining for winter—zip-out for Spring and Fall.

All SMITH-GRAY garments are skillfully tailored to individual measurements.

Send for order-measure form. Four weeks delivery.

Announcing the publication of

DIAGNOSTIC PROCEDURES IN VIRUS AND RICKETTSIAL DISEASES

This handbook, prepared by the Committee on Virus and Rickettsial Diseases of the Laboratory Section and edited by the Chairman of the Committee, Thomas F. Francis, Jr., M.D., details procedures which can be employed and interpreted by laboratory workers in the diagnosis of sixteen virus diseases. The diseases selected are essentially those of man for which procedures are available for use in a diagnostic laboratory.

Each of the sixteen sections has been written by an authority in the field. Much of the experience of each author has been contributed to his chapter and as a result the entire volume constitutes a compilation of methods proved by actual experience.

The volume has grown out of a recognized need for a publication of collected methods and has developed from a round table presentation at the Annual Meeting of the American Public Health Association in 1946. The methods are not presented as standards but are those most currently useful.

Members of the committee who have contributed and their subjects are as follows:

Psittacosis
K. F. Meyer, Ph.D., M.D. and B. Eddie, Dr.P.H.

Lymphogranuloma Venereum
Geoffrey Rake, M.B.

Trachoma and Inclusion Blennorrhea
Phillips Thygeson, M.D.

Variola and Vaccinia
Robert F. Parker, M.D.

Influenza
George K. Hirst, M.D.

MEAT . . .

In the Rational Weight Reduction Program

One dictum is universally recognized in the planning of reducing diets: the basic requirements of good nutrition remain unaltered, and adequate amounts of high-quality protein are the cardinal factor in the successful dietary management of overweight.

Protein allowance in such a program is stated to be not less than 1.5 to 1.7 Gm. per Kg. of ideal body weight.[1] A further advantage of the diet high in protein and low in fat and carbohydrate is its greater simplicity; the tedious calculation of calories may be omitted without impairing the efficacy of the program.[2]

It is therefore recommended that lean meat be given a dominant role in reducing diets.[1]

The protein content of meat is notably high. Regardless of cut or kind, meat provides biologically complete protein able to satisfy the multiple amino acid needs of the body.

Lean meat, particularly, is of excellent digestibility. Its outstanding satiety value assures patient cooperation, a vital factor in the success of any weight reducing program.

DIFCO

Differential Media

BACTO-RUSSELL DOUBLE SUGAR AGAR

- is a very useful aid in the identification of newly isolated strains of the Gram-negative intestinal bacteria. Exceptionally brilliant aerobic and anaerobic fermentation reactions are produced in tubes of this medium. The indicator used is Phenol Red.

BACTO-KRUMWIEDE TRIPLE SUGAR AGAR

- is also recommended in the identification of strains of the colon-typhoid-dysentery group. Atypical strains which produce doubtful reactions on Russell's Agar generally show characteristic reactions in tubes of this medium. Phenol Red is used as the indicator.

BACTO-TRIPLE SUGAR IRON AGAR

- a modification of the Kligler medium combining the fermentation reactions obtained on Krumwiede medium with that of hydrogen sulfide production. It is recommended for routine use in identification of Gram-negative enteric pathogens. Like Krumwiede medium, Bacto-Triple Sugar Iron Agar is prepared with Phenol Red as the indicator of acid production.

BACTO-PHENOL RED MEDIA

- are particularly adapted for determination of the fermentative reactions of bacteria. A selected group of complete agar and broth media containing the more generally used carbohydrates are available as are also the basic media to which any desired sugar may be added. Phenol Red is used as an indicator in these media because of its stability, sensitivity and definite color change from red to yellow in the presence of acid.

BACTO-PURPLE MEDIA

- are new additions to our group of differential media. Bacto-Purple Agar Base and Bacto-Purple Broth Base are excellently suited for preparation of carbohydrate media for study of bacterial fermentation at a slightly acid reaction. The indicator is Brom Cresol Purple and the final reaction of the media will be pH 6.8.

Parke, Davis & Company

ARE PLEASED TO RECORD THE ACHIEVEMENTS LEADING TO THE DEVELOPMENT OF

CHLOROMYCETIN

Trademark (CHLORAMPHENICOL, PARKE-DAVIS)

CHLOROMYCETIN IS A PURE CRYSTALLINE SUBSTANCE HAVING SPECIFIC ANTIBIOTIC ACTIVITY EFFECTIVE AGAINST AN IMPRESSIVE ARRAY OF MICRO-ORGANISMS

In the history of CHLOROMYCETIN, chance has played little part. Starting from past knowledge of antibiotic activity in soil organisms, thousands of soil samples were collected throughout the world, cultured, and screened for antibiotic properties. Definite activity was found in cultures of *Streptomyces venezuelae*, an organism named for its place of origin. The active antibiotic was then isolated in pure form. Its chemical configuration was determined and reproduced by synthesis. CHLOROMYCETIN is therefore the first antibiotic for therapeutic use that can be produced in quantities by both natural and chemical methods.

The important indications for CHLOROMYCETIN, *thus far, include:*

UNDULANT FEVER
BACILLARY URINARY INFECTIONS
PRIMARY ATYPICAL PNEUMONIA
TYPHOID FEVER
TYPHUS FEVER
SCRUB TYPHUS
ROCKY MOUNTAIN SPOTTED FEVER

CHLOROMYCETIN can be administered efficiently by the oral route, yielding effective blood levels. It is supplied in Kapseals of 0.25 Gm.

Descriptive literature will be mailed on request.

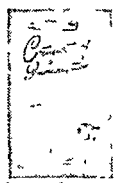
Acceptance for mailing at the special rate of postage provided for in Section 1103, Act of October 3, 1917.

"Alhydrox"®

means



ALUMINUM HYDROXIDE ADSORBED

"Alhydrox" is a handy contraction doctors are also using oftener these days. To them it describes a *plus value* in Cutter immunization products.

What "Alhydrox" does—The selectivity of aluminum hydroxide controls the adsorption of antigens, thus reducing dosage while maintaining a high antibody concentration. After injection the "Alhydrox" adsorbed antigens are released gradually, prolonging stimulation through slow absorption.

What "Alhydrox" means to doctors and their patients—Alhydrox assures doctors of higher antitoxin levels that are longer lasting. The favorable pH of aluminum hydroxide lessens pain on injection and cuts side reaction to a minimum. Rare indeed are crying youngsters and nervous mothers (fathers, too) who complain about reactions like persistent nodules.

CUTTER'S NEW CERTIFICATE OF IMMUNIZATION has been so popular with doctors and nurses the country over that the first big quantity printed ran out in a hurry. More are being printed now and can be procured, free of charge, by asking your Cutter detail man or writing Cutter Laboratories, Berkeley, California. Dept. D-9

- **Pertussis Phase I Alhydrox**
  30,000 million H pertussis per cc.
- **Diphtheria Toxoid Alhydrox**
- **Tetanus Toxoid Alhydrox**
- **Diptussis Alhydrox®**
  Cutter Diphtheria Toxoid plus 20,000 million H pertussis per cc., for simultaneous immunization against pertussis and diphtheria.
- **Diphtheria Toxoid–Tetanus Toxoid Alhydrox**
  For simultaneous immunization against diphtheria and tetanus.
- **Dip-Pert-Tet Alhydrox***
  Cutter diphtheria, pertussis, tetanus combined vaccine for simultaneous immunization against diphtheria, pertussis, tetanus.

The "Shattuck Report"

Republished for the first time!

"One of the most remarkable documents—perhaps the most significant single document in the history of Public Health."
C.-E. Amory Winslow

Report of the Sanitary Commission of Massachusetts: 1850

By Lemuel Shattuck and Others

THIS is the famous first general plan for the promotion of public health to be presented to an American governmental body, and its influence over the whole field ever since that time can hardly be exaggerated. The "Shattuck Report" made fifty specific recommendations regarding sanitation, recording of vital statistics, protection of school children, medical research, nurses' training, slum clearance, and other problems vital to the increase of the mean expectation of life in the United States. Its first proposal was for the creation of state and local boards of health in an era when such state commissions were non-existent.

Lemuel Shattuck (1793–1859) was a business man—a bookseller and publisher—whose important public services include plans for the recording and preservation of public documents, and the establishment (due to his efforts) of the Massachusetts System for the registration of births, deaths, and marriages. In 1839 he was one of the founders of the American Statistical Association.

Now republished for the first time since its original release in 1850, this facsimile edition of the "Shattuck Report" again makes it available to everyone interested in medicine, public health, or the vital statistics and social conditions of the mid-nineteenth century. It is sponsored by the American Public Health Association, the Massachusetts Public Health Association, the Harvard Graduate School of Public Health, the Massachusetts Department of Public Health, and the Boston Health Department. *ix + 321 pages, $4.50*

NEW BOOKS FOR THE PUBLIC HEALTH OFFICER

Zacks: Photoradiography in Search of Tuberculosis.

Twenty years of experience in the control of tuberculosis by clinics, surveys and conferences form the basis for the material in this book. It should be required reading for any group contemplating mass radiography, because its warnings on avoiding trouble are clear, its attention to detail meticulous, and its aid in making case findings a permanent part of each community commendable. In introducing mass chest radiography to the civilian population the author prefers a sustained, systematic attack. Emphasis is placed on planning the campaign so that it contributes to furthering tuberculosis research. (Publication scheduled for April.)

Approximately 400 pp., 274 figs., price to be announced.

Fairhall: Industrial Toxicology.

In this reference manual of toxicology, the author describes the toxicity of new as well as old substances used in industry. Under each heading he discusses characteristics, industrial uses, toxicity and analysis, and lists pertinent references. The text material is divided into two groups—inorganic substances and the carbon compounds. Substances in each group are then arranged alphabetically for greater ease in reference. 400 pp. (1949) $6.00.

Coburn and Young: Epidemiology of Hemolytic Streptococcus.

This is the first and only well-controlled study of such huge proportions ever to be reported. It presents the work done by the Epidemic Disease Control Section of the Division of Preventive Medicine, U. S. Navy, of which Dr. Coburn was the director. Many valuable lessons for the control of civilian epidemics can be learned from the Navy experience. 236 pp., 31 figs. (1949) $5.00.

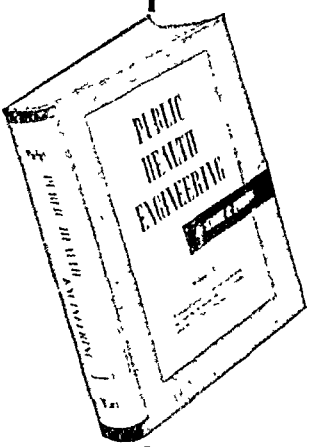
Frazer and Stallybrass: Textbook of Public Health. Twelfth Edition.

This is as complete a text as could be desired. Included are chapters on industrial hygiene, water, sewage disposal, and housing. Maternity and child welfare and school medical service are minutely described. Of great interest are the chapters on marine hygiene and hospital administration. There is a new chapter on social services.

582 pp., 78 figs. (1948) $8.50.

Currie and Mearns: Hygiene, A Manual of Public Health. Third Edition.

The momentous changes in the field of medicine in the last few years have made necessary a more comprehensive treatment of the subject matter, and an expansion of the fields covered. The book has undergone complete revision and been greatly enlarged. New sections are those on health education and medical climatology.



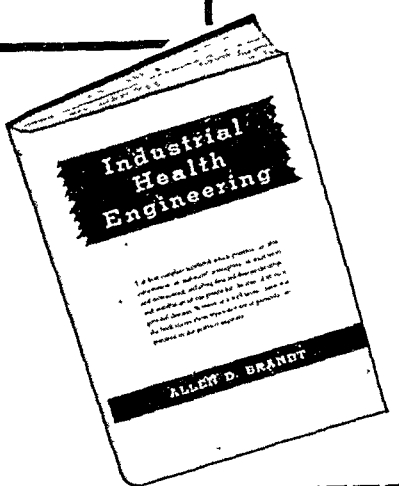
744 pp., 212 figs., 4 color plates (1948) $9.00.

THE WILLIAMS & WILKINS COMPANY

Mt. Royal and Guilford Aves. Baltimore 2, Maryland

Two authoritative books on public and industrial HEALTH problems

PUBLIC HEALTH ENGINEERING



Volume I

By EARLE B. PHELPS, Professor Emeritus of Sanitary Science of the School of Public Health, College of Physicians and Surgeons, Columbia University, and Professor of Sanitary Science, College of Engineering, University of Florida.

In *Public Health Engineering,* the author presents a unified treatment of environmental sanitation. Volume I concentrates on two major factors, air and water. The author explains, in the light of present day knowledge of sanitary science, what protective devices to build, and why they are chosen. The trained engineer will find the emphasis on the public health aspect especially valuable. Chemistry and the biological sciences form the approach to the subject. For this reason, the book is also particularly useful to the medically trained student of public health.

1948 656 pages illustrated $7.50

INDUSTRIAL HEALTH ENGINEERING

By ALLEN D. BRANDT

Medical Division, Bethlehem Steel Company

This book shows how to recognize the health hazards of various industries, and makes concrete suggestions on how to combat them. INDUSTRIAL HEALTH ENGINEERING lists over 1,000 hazardous occupations, from balloon inflators to straw-hat makers. Each occupation is indexed for quick reference to a table of health hazards that tells in details just what the job dangers are. Using these tables with the text, it is easy to determine not only what specific jobs in a particular industry are dangerous, but also why—and what can be done to make them safe.

How can men eat "good" meals— and still be undernourished?

Mineral Nutrition of Plants and Animals

By Frank A. Gilbert

Battelle Memorial Institute

"HIDDEN HUNGER" lurks in the food we eat. . . . Healthy men require healthy foods adequately fortified with proper minerals. In this important survey, you will find discussions of many books and articles dealing with mineral nutrition. A noteworthy addition to the mounting literature on the values of trace elements to plants and animals, it classifies mineral elements in nutrition and presents a sketch of the early history of plant nutrition—from Aristotle to Liebig. Here you will find the answers to such questions as: What causes low crop production, abnormally developed plants? "Hairless" hogs? Lean livestock?

This important adjunct to source material in the field of nutrition serves as a foundation for more intensive research in seeking better food for the health of the nation. 144 pages, fully documented with illustrations and an excellent bibliography. $2.75

THE FOOD YOU EAT:

A Practical Guide to Home Nutrition

By Samuel and Violette Glasstone

Completely keyed to today's food realities, this book by one of the foremost scientists and his wife includes necessary diets for healthier living. "Solid, helpful information."—*American Cookery. Illustrated*, $2.25

WHAT TO DO ABOUT VITAMINS *By Roger J. Williams*

Director of Biochemical Institute, Univ. of Texas

Authoritative guide to vitamins and minerals, how they are necessary in the diet and how they may be secured in wholly adequate quantities. Profusely illustrated with tables, graphs, and charts. $1.00

ESSENTIALS OF NURSING

By HELEN YOUNG, ELEANOR LEE and ASSOCIATES

Second Revised Edition

Although this book was intended especially for students, its emphasis on the Sociological and Psychological aspects of nursing fit it admirably in furnishing graduate nurses with a modern reference and review volume. Price $3.75

NURSING IN PREVENTION AND CONTROL OF TUBERCULOSIS

By H. W. HETHERINGTON and FANNIE ESHLEMAN

A notable text for students and an outstanding reference work for all public health workers prepared by two exceptionally well qualified authors. Price $3.50

G. P. Putnam's Sons • 2 West 45 Street, New York 19

Publishers for Nurses since 1878

New Mosby Books

IN THE FIELD OF PUBLIC HEALTH

- **Turner's PERSONAL AND COMMUNITY HEALTH**

  New Eighth Edition. With the help of suggestions from many specialists, this book has been thoroughly revised and brought up to date. New material includes a self-appraisal chart for evaluating personal health. There has been a thorough reorganization of the material on communicable diseases with the addition of a new chapter on this subject. The latest statistical data in the field of public health is included.

  There are new sections dealing with such topics as voluntary health agencies, new developments in nutrition, the Rh factor, DDT, new insect repellants, new antibiotics, gamma globulin, and many other developments in the field of health and preventive medicine. 568 pages, illustrated. (1948) Price, $4.00

- **Turner's SCHOOL HEALTH AND HEALTH EDUCATION**

  This book presents a picture of the modern school health program from the standpoint of its opportunities for health education. It is written for the course in School Health or in Health Education in the Teachers' College and for the teachers in service. Methods, curriculum building, source materials and other phases of health education are presented in detail.

  Its scope is broad and authoritative and its use will improve health programs—as well as the relations between directors and personnel. 457 pages. (1947) Price, $3.50

- **Cureton's PHYSICAL FITNESS, APPRAISAL AND GUIDANCE (With Collaborators)**

  Dr. Cureton and his associates have measured the physical fitness of thousands of normal young men and women on the Urbana Campus of the University of Illinois and have demonstrated differences in scoring, undoubtedly interpretable in terms of health levels. This book is the record of these experiments. It was written with the hope that it will help others in similar appraisals of their students—and that it will help to standardize the methodology of such work. 566 pages, illustrated. (1947) $6.00

- **Cureton's PHYSICAL FITNESS WORKBOOK**

  A Manual of Conditioning Exercises and Standards, Tests and Rating Scales for Evaluating Physical Fitness.

  Profusely illustrated, this manual contains complete descriptions of the exercises and conditioning activities that are recommended. With its use individual records may be kept evaluating personal progress in physical fitness. One of the most important inclusions in this workbook is the series of rating scales based on the most modern statistical procedures and in line with the most approved educational use for such scales. 150 pages, illustrated. (1947) $2.50

- **O'Keefe-Fahey's EDUCATION THROUGH PHYSICAL ACTIVITIES**

  The purpose of this book is to provide comprehensive materials, suggest teaching procedures and techniques, and discuss ways of evaluating programs of physical education and recreation. Suggestions and plans are submitted in nontechnical terms in order that they may be used by classroom teachers, recreational leaders, and parents, as well as by specialists. Special attention is brought to activities that contribute to the development of the upper portion of the body and to activities and equipment for out-of-school use. 325 pages, illustrated. (1949) Price, $4.00

- **Top's COMMUNICABLE DISEASES**

  Second Edition. Every chapter in this edition has been revised and improved. Three chapters have been completely rewritten: Influenza, Malaria, and Rickettsial Diseases. It contains fourteen new chapters as follows: Coccidioidomycosis, Rheumatic Fever, Primary Atypical Pneumonia, Epidemic Diarrhea of the Newborn, Infections Hepatitis, Chancroid, Lymphogranuloma Venereum, Granuloma Inguinale, Ophthalmia Neonatorum, Epidemic Keratoconjunctivitis, Leptospiral Jaundice, Ringworm of the Scalp, Trachoma and Infectious Mononucleosis. 947 pages, 98 illustrations, 13 color plates. (1947) Price, $9.50

Announcing

two significant McGraw-Hill books for every public health worker

Now in preparation

Lemkau's MENTAL HYGIENE IN PUBLIC HEALTH

By PAUL V. LEMKAU, M.D., Associate Professor of Public Health Administration and Director of the Mental Hygiene Study, Johns Hopkins School of Hygiene and Public Health.

The important and practical relation between mental hygiene and public health is described in this new book designed to give public health workers effective techniques and programs for promoting and protecting the mental health of the population in their everyday work. Dr. Lemkau traces the development of the personality, demonstrating at each stage the possibilities for modification in the direction of better mental health.

McGraw-Hill Series in Health Science
Approximately 450 pages, 6 x 9, illustrated.

Bridge's EPILEPSY AND CONVULSIVE DISORDERS IN CHILDREN

By EDWARD M. BRIDGE, M.D., Research Professor of Pediatrics, School of Medicine, University of Buffalo; Director of Research, Children's Hospital of Buffalo; formerly Associate in Pediatrics, Johns Hopkins School of Medicine.

Ready soon

A presentation of experiences accumulated in the Epilepsy Clinic at Johns Hopkins over a period of fifteen years. This practical book emphasizes the psychiatric and sociological aspects of the disease as well as the more purely medical problems. Details of practical management of afflicted children and the problems of caring for them at home, in school and in the community are among the special features of the book.

McGraw-Hill Series in Health Science
Approximately 550 pages, 6 x 9, illustrated.

SYPHILIS: IT'S COURSE AND MANAGEMENT

This book explains clearly the new quick-treatment of syphilis through the use of penicillin. The book is based on the findings of the author who has been director of the Rapid Treatment Center, Bellevue Hospital, since its inception in 1944. It provides undergraduates and practitioners alike the latest needed knowledge of methods of diagnosis, prognosis, and treatment.

Evan W. Thomas, M.D.

To Be Published in April

THE VENEREAL DISEASES, 2nd ed.

This new second edition offers the latest information on the treatment of the venereal and allied diseases. It includes information on the use of penicillin as well as the latest advances in arsenotherapy. Excellent illustrations along with masterful text presentation make this a practical book for practitioner or student.

James Marshall, M.D.

369 pp. Illus. $5.50

TAKING THE CURE

A practical guide for the tuberculosis patient. The author, once a patient himself, explains in simple language what tuberculosis is and how it is cured. He gives practical suggestions on how to be comfortable in bed and how best to get accustomed to various clinical procedures as well as how to make the needed mental adjustment.

Robert G. Lovell, M.D.

93 pp. Illus. $2.00

PREVENTIVE MEDICINE AND PUBLIC HEALTH

The modern concept of preventive medicine applied to private practice! The author stresses the important function of the private physician with regard to the public's health and shows how his work is linked with the public health agency. Included are sections on such subjects as Bio-Statistics; Promotion of Child Health; Social and Economic Factors and Their Influence Upon Disease, etc.

Wilson G. Smillie, M.D.

607 pp. $6.00

PUBLIC HEALTH ADMINISTRATION IN THE UNITED STATES, 3rd ed.

A source book of prevailing and recommended principles and practices in public health administration. It offers the latest information on the administrative control of communicable diseases, basic activities of a health organization, and public health programs.

Wilson G. Smillie, M.D.

637 pp. Illus. $6.50

AN INTRODUCTION TO PUBLIC HEALTH, 2nd ed.

A background text for all beginning students in public health. It clearly defines problems and analyzes programs and practices in the field of public health. Only facts that will prove most useful in orienting the student and helping him to develop sound perspectives are considered.

Harry S. Mustard, M.D.

283 pp. $3.50

COMMUNICABLE DISEASE CONTROL

One of the most authoritative books on this subject written to date. It discusses in detail the various control measures utilized for protection of the community's health and the relative effectiveness of these measures. The diseases chosen for discussion are those of greatest interest to most communities in the United States and Canada. Emphasis is on procedures that protect the population as a whole rather than on protection of the individual.

Gaylord W. Anderson, M.D. and Margaret G. Arnstein, R.N.

450 pp. Illus. $5.00

When writing to Advertisers, say you saw it in the JOURNAL

The book that has saved time, trouble and money for thousands of doctors and clinics

Expectant Motherhood

By Dr. Nicholson J. Eastman

Professor of Obstetrics in Johns Hopkins University and Obstetrician-in-Chief to the Johns Hopkins Hospital

TWENTY big printings since publication show what EXPECTANT MOTHERHOOD means to the busy obstetrician; show how this book has won its way to a leading position in medical literature. More and more doctors every day are ordering and re-ordering EXPECTANT MOTHERHOOD for their patients. You too can save time, money and trouble with EXPECTANT MOTHERHOOD, the complete, calm, understanding, authoritative and reassuring guidebook through pregnancy that has won unstinted praise from doctors everywhere.

Here's what Doctors say:

● "I consider it one of the outstanding contributions in the field and recommend its reading freely."—DR. GEORGE W. KOSMAK, *Editor of American Journal of Obstetrics and Gynecology.*

● "A copy of this book is given to each new obstetric patient upon her first consultation and is most enthusiastically received. The information contained . . . RELIEVES ME OF NUMEROUS TELEPHONE CALLS."—DR. CUTHBERT POWELL, *Consulting Gynecologist, Denver General Hospital.*

● "It is the best book in this field. I use it constantly in my practice."—DR. HERBERT F. TRAUT, *Obstetrician and Gynecologist in Chief, University of California Hospital.*

● "With Dr. Eastman's EXPECTANT MOTHERHOOD in the home both the patient and the father-to-be have a wealth of correct information available at all times. It helps reduce nuisance symptoms and complaints to a minimum and therefore is A TIME SAVER FOR THE PHYSICIAN!"—DR. FREDERICK C. FREED, *Clinical Professor of Obstetrics and Gynecology, New York University Medical School.*

● "We have been using Eastman's EXPECTANT MOTHERHOOD ever since it was first published. Our patients find it very helpful and we consider it a valuable aid in our prenatal care."—DR. GEORGE KAMPERMAN, *Chief Obstetrician and Gynecologist and Chief of Staff, Harper Hospital, Detroit, Michigan.*

● "In my opinion, this is by far the best book on the subject."—DR. EMERSON L. STONE, *Associate Clinical Professor of Obstetrics and Gynecology, Yale University.*

DOES YOUR CITY
KNOW ITS HOUSING PROBLEM?

Just where and how big are the slums? How substandard are they, and in what ways?

Can part of the problem be solved by enforcement of reasonable housing codes?

What families need new housing, and how much can they pay for it?

These and other basic questions of housing policy can be answered with data from

AN APPRAISAL METHOD FOR MEASURING THE QUALITY OF HOUSING:

A Yardstick for Health Officers, Housing Officials and Planners

This is the survey technique, developed by the American Public Health Association's Committee on the Hygiene of Housing, of which Abel Wolman has said:*

> "It is one of the major contributions to translating opinion into objective measurement in one of the most difficult fields of appraisal."

Officially adopted by health departments in cities ranging from Battle Creek and Brookline to Milwaukee, St. Louis and Los Angeles, this method is now being promoted by the U. S. Public Health Service.

The Method is Completely Described in the Following Publications:

Part I. NATURE AND USES OF THE METHOD $1.00
This introductory volume is written for the policy-making official. In 53 readable pages, with many illustrations, it tells how practical housing programs can be shaped from an objective survey.

Part II. APPRAISAL OF DWELLING CONDITIONS $5.00
Three separate manuals give step-by-step instructions to the local survey director, the field crew and the office staff of a dwelling survey.

Part III. APPRAISAL OF NEIGHBORHOOD ENVIRONMENT In Press
Similar instructions are given for measuring the physical adequacy of neighborhoods.

Now—the Personal Approach to Public Health

HOW TO LIVE LONGER

by Justus J. Schifferes, Ph.D.

Formerly instructor in health education, Teachers College, Columbia University
With a Foreword by Ralph F. Sikes, M.D., M.P.H.

Lively, authoritative, comprehensive
A vital new book to read and recommend

HERE is a book that may help to prolong your own life. Professionally recommended, it will help you in your task of preventing the 250,000 untimely deaths—"involuntary suicides"—that occur in the U. S. each year.

AUTHORITIES and critics praise it highly. Dr. Frank Slaughter in *The New York Times* said: "It should certainly attract many readers of all ages. . . . Deals with the most important phase of disease control, health education. . . . Gives in simple words the latest information now available." . . . Morris Fishbein, M.D., editor of the *Journal of the American Medical Association*, writes: "I find it exceedingly readable with some new presentation of data about medicine and health that will be most helpful." . . . Charles C. Wilson, M.D., Professor of Education and Public Health at Yale University declares, "An interesting story . . . Modern concepts of important health problems are presented in clear language". *Modern Medicine* said: "Helpful . . . tells enough but not too much."

St. Louis Post Dispatch review said: "REFRESHING in its air of substance and authority. . . . Robs statistics of their dry-as-dust complexion. . . . Perfectly clear. . . . Not a book of home remedies. . . . The essence of this book is the orderly discussion of the 11 principal causes of death in our country: Heart disease, cancer, apoplexy, accidents, kidney disease, pneumonia, tuberculosis, premature birth, diabetes, suicide and syphilis. . . . It is to Dr. Schifferes' lasting credit that he teaches this without scaring the daylights out of his readers."

READ *How to Live Longer* for your own protection and recommend its adoption as a useful text for *adult health education* and in colleges. Order today. Get 25 percent discount by using coupon below. Clip and send immediately to

105,000 Copies Already Distributed!

Suggested SCHOOL HEALTH POLICIES . . 2nd edition revised

by the National Committee on School Health Policies

In Japan it is counteracting effects of the atomic bomb... How many copies can you use in America?

AMERICAN military government teams in Japan have ordered SUGGESTED SCHOOL HEALTH POLICIES to help them rehabilitate the Japanese school system. Fifteen copies went to atom-bombed Nagasaki. A staff member of the Hyogo Military Government Team sent an order in February, 1949.

SUGGESTED SCHOOL HEALTH POLICIES has now crossed the traditional mark of the "best-seller"—an astonishing achievement for a health publication. More than 105,000 copies have been distributed. Orders have come from Canada, England, Hawaii and Peru. In the United States, in Arkansas alone, 9,000 copies were distributed through the State Board of Health! But every state has ordered.

QUANTITY purchasers have included the American Public Health Association, the American Medical Association, the National Tuberculosis Association as well as state, county and city Boards of Health and Boards of Education and local chapters of voluntary health agencies.

A personal copy of SUGGESTED SCHOOL HEALTH POLICIES for reading, study and reference should be in the hands of every public health nurse and every school teacher—as well as administrative officials and many parents of school children. "Recommended to all persons concerned with public health in schools," said the *New England Journal of Medicine.*

SUGGESTED SCHOOL HEALTH POLICIES is the work of a committee representing 15 major organizations concerned with health and education in the United States. It is the accepted, standard guide for putting effective school health policies into action. Put it to work in your schools and community. How many copies do you need? 35 YEAR INDEX OF AMERICAN JOURNAL OF PUBLIC HEALTH

Volumes 1 to 35 for the Years 1911 to 1945

AUTHORS AND SUBJECTS

All of the literature published on a given subject in the Journal during the years 1911 through 1945 will be found in one place. The Index makes available a vast storehouse of valuable information contained in the fifty thousand pages published during this period.

The Index covers original papers, editorials, committee reports and matters pertaining to the Association. Titles have been examined for all key words so that each title should be sufficiently cross indexed. Every page in the 35 volumes indexed was examined. The yearly indexes were used as a check against the entries.

The tremendous task of preparing the Index was done by Louise Pickens Tanner and Fred Wilbur Tanner, who are experienced workers in science possessing the knowledge and appreciation of care and accuracy so necessary in an effort of this kind.

The American Public Health Association has authorized the preparation and publication of this cumulative index and recommends it as a valuable addition to the libraries of all public health workers.

announce for this Spring

the first Newsweek book

MEDICINE ON THE MARCH

A PROGRESS REPORT

by Marguerite Clark

Head of Newsweek's Medicine Department

→MARGUERITE CLARK is an executive editor in the National Association of Science Writers — and one of the few women members. Her specialization has made her one of the twenty competent science writers in the country; her book the kind of reporting that has won her the confidence of the entire professional world "for consistently accurate, informative articles on medicine."

DURING the five-year war period American medicine advanced 25 years. The 18 chapters of this book, each a separate report on a separate medical condition, cover the work of hundreds of top medical specialists and researchers in America and include the latest treatments, surgical techniques and drugs that have been used with success — telling by whom, where, and what the future promises. The book covers heart ailments . . . high blood pressure . . . cancer . . . tuberculosis . . . infantile paralysis . . . psychiatry . . . child mental health . . . epilepsy . . . surgery . . . new drugs . . . allergy . . . rehabilitation . . . special rehabilitation of hemaplegics and paraplegics . . . pediatrics . . . geriatrics . . . alcoholism . . . atomic medicine. Here is straight, down-to-facts medical reporting that the layman can trust.

At all bookstores, $3.50

Announcing the publication of

DIAGNOSTIC PROCEDURES IN VIRUS AND RICKETTSIAL DISEASES

This handbook, prepared by the Committee on Virus and Rickettsial Diseases of the Laboratory Section and edited by the Chairman of the Committee, Thomas F. Francis, Jr., M.D., details procedures which can be employed and interpreted by laboratory workers in the diagnosis of sixteen virus diseases. The diseases selected are essentially those of man for which procedures are available for use in a diagnostic laboratory.

Each of the sixteen sections has been written by an authority in the field. Much of the experience of each author has been contributed to his chapter and as a result the entire volume constitutes a compilation of methods proved by actual experience.

The volume has grown out of a recognized need for a publication of collected methods and has developed from a round table presentation at the Annual Meeting of the American Public Health Association in 1946. The methods are not presented as standards but are those most currently useful.

Members of the committee who have contributed and their subjects are as follows:

Psittacosis
K. F. Meyer, Ph.D., M.D. and B. Eddie, Dr.P.H.

Lymphogranuloma Venereum
Geoffrey Rake, M.B.

Trachoma and Inclusion Blennorrhea
Phillips Thygeson, M.D.

Variola and Vaccinia
Robert F. Parker, M.D.

Influenza
George K. Hirst, M.D.

Primary Atypical Pneumonia
A. E. Feller, M.D.

SEX FULFILLMENT IN MARRIAGE

By Ernest R. Groves, Gladys Hoagland Groves, and Catherine Groves

"Rarely has it been the reviewer's privilege to read a book which he can so whole-heartedly endorse as this latest volume by the Groves'."—*American Sociological Review*

"The scientific and yet easily readable approach to this subject makes this a volume that can be widely recommended."—*Journal of the American Medical Association* $3.00

SEX LIFE IN MARRIAGE

By Dr. Oliver M. Butterfield

"This book . . . discusses the sexual side of marriage with frankness and clearness."—*Church Management*

"The best manual to give."—*Ohio State Medical Journal* $2.00

SEX TECHNIQUE IN MARRIAGE

By Isabel Emslie Hutton, M.D.

"'A clear, succinct, non-emotional, authoritative and conservative exposition of the practical factors involved in making marriage successful on the sexual level.' That describes the book exactly."—*Hygeia* $2.00

SEX EDUCATION: A Guide for Parents, Teachers and Youth Leaders

By Cyril Bibby

"It would be hard to find a sounder and better balanced discussion of the subject."—*Family Life Education.*

"Contains a wealth of essential information and teems with practical suggestions."—*The Bulletin of the National Association of Secondary-School Principals* $2.50

HOW LIFE IS HANDED ON

By Cyril Bibby

"A wonderful book for adolescents, to explain reproductive systems of man and beast. The style of writing is easy and direct. Illustrations are informative and ample. The book explains things as most parents wish they could."—*Journal of the American Medical Association*

"In this charmingly written book Cyril Bibby has made a real contribution to the literature in this field. It is intended primarily for children and young adolescents, but parents, teachers, and youth leaders will find it invaluable."—*Journal of Social Hygiene* $2.00

VD MANUAL FOR TEACHERS

By Samuel D. Allison, M.D., and June Johnson

"Recommended as a constructive, intelligent and welcome contribution in the field of public health education."—*Quarterly Review of Biology*

"A very welcome help to teachers in a field which has been neglected much too long in far too many places." — *Bulletin of the Johns Hopkins Hospital* $2.00

PSYCHOLOGY OF SEX

By Havelock Ellis

"The best of all available books on this subject."—*Hygeia*

"Written in clear interesting fashion—good literature as well as good science, from a man who knows sociology and human relationships as well as biology and medicine."—*Journal of Social Hygiene* $3.00

PREPARATION FOR MARRIAGE

By Ernest R. Groves

"Thought-provoking and convincing. . . . Written in simple, friendly language, presenting the various aspects of marriage with a wholesome, outspoken seriousness."—*Mental Hygiene* $1.75

SEX EDUCATION IN HIGH SCHOOLS

By John Newton Baker

"As important to mental hygiene and psychiatry as to social hygiene and sociology, and psychiatric workers will find (this) book both instructive and interesting."—*Psychiatric Quarterly* $2.00

YOUR SKIN AND ITS CARE

By Howard T. Behrman, M.D., and Oscar L. Levin, M.D.

"The type of book to which the physician can refer his patients who want more information than can be obtained during the average consultation session."—*Journal of the American Medical Association*

"The sound advice contained in this book should do much to insure a healthy complexion by directing the reader's thoughts into proper channels, both as to the cause of the complaint, and as to the remedial measures necessary for its correction."—*Connecticut State Medical Journal*

"Offers in readable style facts on some of the problems that plague people; it explains the how and why."—*Hygeia* $2.50

BEAUTY PLUS

By Mary MacFadyen, M.D.

"The author . . . seems to have caught the idea of making sound hygiene attractive. The book is cleverly illustrated and is a most interesting volume of general advice for women on health, beauty, recreation and the sex life."—*Journal of the American Medical Association* $2.49

THE HYGIENE OF THE BREASTS

By Clifford F. Dowkontt, M.D.

"This much-needed treatise on a too-little-understood subject is most welcome."—Beulah France, R.N. in *The American Baby*

"A very commendable job for the laity." — *Connecticut State Medical Journal* $2.50

EMERSON BOOKS, INC.
251 West 19th St. New York 11, N. Y.

Did you know that

less than sixty years ago tomatoes were thought to cause cancer; kerosene lamps were just coming into use; eggs were 8 cents a dozen—butter 12 cents a pound?

Dr. Crumbine, from the *New Yorker*

FRONTIER DOCTOR

by Samuel J. Crumbine, M.D.

reminisces about these and other amazing facts about his practice as a frontier physician and pioneer health officer in Dodge City, Kansas in the 1880's. Dr. Crumbine, as State Health Officer for Kansas did a notable job for that state and the nation waging a planned warfare against houseflies and rats, the common drinking cup and roller-towel and for many of the progressive steps in public health in America. Don't miss the vigorous, photographic story of this pioneer in health. **$3.00**

Announcing Two New Publications . . .

CHILD HEALTH SERVICES AND PEDIATRIC EDUCATION

The nation-wide survey of the Committee for the Study of Child Health Services of the American Academy of Pediatrics, with the cooperation of the U. S. Public Health Service and the U. S. Children's Bureau.

The first study of this type ever undertaken, this is a comprehensive inventory and analysis of the services of physicians and dentists in private practice, of hospitals and community health agencies, both official and voluntary, and pediatric education.

$3.50

OFFICE MANAGEMENT FOR HEALTH WORKERS

By Frances King & Louis L. Feldman

This practical book adapts the principles of established office practice to the needs of a health department office or voluntary agency, and it provides for the first time a reference text for the health administrator and a guide for the training of all workers in the field of public health. It gives special attention to management and personnel problems, equipment needs, and various kinds of records and systems of record-keeping and filing.

$2.25

Other Public Health Books

PUBLIC HEALTH LAW . *1947 Revised Edition*

By James A. Tobey, Dr.P.H., LL.D.

The third edition of this standard work on public health law has been expanded to include approximately 250 new court decisions, recent alterations in governmental organization and administration, and important legislative trends. Written especially for health officials, teachers of public health, and attorneys. *440 pages, $4.50*

MILK AND FOOD SANITATION PRACTICE

By H. S. Adams

A practical text in the field of environmental sanitation designed to help public health engineers and sanitarians bridge the gap between theory and practice—between what should be done and how to do it. The essential and fundamental principles of milk and food control are presented with special emphasis on the practical and educational application of these principles in the sanitary supervision of such supplies. *328 pages, $3.25*

GOVERNMENT IN PUBLIC HEALTH

By Harry S. Mustard, M.D.

Dr. Mustard traces the development of public health service in the United States from social and governmental standpoints. He deals with the complex relationships of federal, state, and local health services and points up the health problems of today. He delineates public health service as it is, projects probable trends into the future, and considers the effects of these potential developments. *235 pages, $1.50*

FOR DOCTORS, NURSES, PUBLIC OFFICIALS
A TRULY INVALUABLE BOOK!

BURN
Recent Advances in Public Health

TWO decades of progress in preventive medicine as it relates to the individual and to his community are here summarized. The book is arranged in three main parts—Public Health and the Individual, Public Health and the Community and Public Health and the Environment. Some of the subjects treated are Public Health Nursing, Care of Handicapped Children, Welfare of the Aged, Poverty, Vaccination Methods, Verminous Infestation, Water Purification, Smokeless Air and Refuse Disposal. A compact, handy volume which covers the field up to the present—will prove to be an invaluable aid in solving and understanding today's Public Health problems.

FUNDAMENTALS OF HEALTH AND SAFETY

MUELLER and ROBERTSON

This new high school text reaches out directly to the student. The style is personal. Here is information in straight-forward language about the most fascinating person in the world to the student—himself.

Health and Safety is short. It can be completely covered in the time usually allotted the student. For all its brevity, the book includes every essential of health education needed by the average course.

The authors are practical people. Grover Mueller is Philadelphia's Director of Physical and Health Education, and also teaches at Teachers College, Temple University. Dr. Elizabeth Chant Robertson, former Fellow in Hygiene at The Johns Hopkins University, is now in the Department of Paediatrics, University of Toronto. The text, therefore, combines the viewpoints of public school and hospital, teacher and physician.

Illustrations and diagrams are ample. End-of-chapter material is rich. 343 pages—$2.40

If you are changing texts, please let us know.

SANITARY ENGINEERING BACKGROUND

The QUEST *for* PURE WATER

by

M. N. BAKER

Here, at long last, is a comprehensive history of water purification from the earliest records to the twentieth century, relived and recorded by M. N. Baker following his retirement as Associate Editor of *Engineering News Record* in 1932. Here, as Abel Wolman says in his foreword, is "an inexhaustible treasury of authenticated information," which no student of sanitary engineering can afford to miss.

The product of nine full years of research after forty-five years of first-hand observation, Mr. Baker's story of man's 4,000-year "Quest" for a pure supply of drinking water is a must, not only for your library but for your reading list. Implementing his text with 73 illustrations from the history of water treatment, the author has also provided an invaluable documentation of 900 references in a separate bibliography.

ZINSSER'S
TEXTBOOK *of* BACTERIOLOGY

(formerly Hiss, Zinsser and Bayne-Jones)

By

David T. Smith, M.D., Professor of Bacteriology and Assoc. Prof. of Medicine and
Donald S. Martin, M.D., M.P.H., Prof. of Prev. Med. and P.H., and Assoc. Prof. of Bacteriology

With

Norman F. Conant, Ph.D., Professor of Mycology and Assoc. Prof. of Bacteriology
Grant Taylor, M.D., Assoc. Prof. of Bacteriology and Assoc. Prof. of Pediatrics
Joseph W. Beard, M.D., Professor of Surgery in Charge of Experimental Surgery
Henry I. Kohn, M.D., Assoc. Professor of Physiology and Pharmacology
Mary A. Poston, M.A., Instructor in Bacteriology

All from Duke University School of Medicine

FUNDAMENTALS, TECHNICS, PRACTICAL APPLICATIONS

In its first revision in 9 years this famous text has been extensively rewritten and wholly revised to bring it right down to date as a modern presentation of the fundamentals and technics of bacteriology, mycology and immunology. Includes the biological characteristics and the reactions of living tissues to the bacteria and their products with bold face type used to emphasize the important biological and cultural characteristics.

The new authors functioning as a research-teaching-clinical team have incorporated a great deal of the published and unpublished knowledge developed during the scientifically profitable war and post-war years.

The discussion of the sulfonamides has been expanded and a section on antibiotics added. An important new chapter discusses pleuro-pneumonia-like organisms.

One hundred eighty-two new illustrations have been added, including many electron micrographs, to illustrate submicroscopic morphological details of bacteria and viruses.

Published August 1948.

9th Edition. Rewritten, Revised and Reset. 1032 pages. 264 illus. $10.00

Presenting the

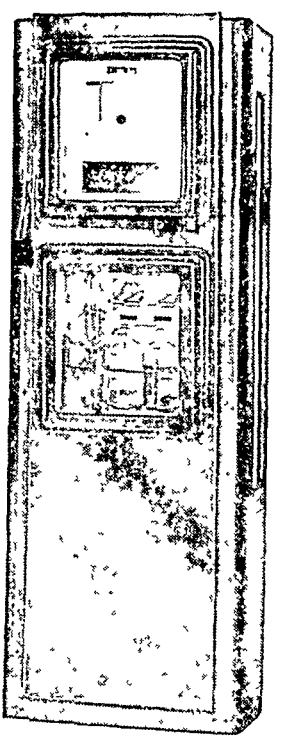
W&T RESIDUAL CHLORINE RECORDER

Culminating 35 years' leadership in chlorination, W&T now offers the Amperometric Residual Chlorine Recorder to water works operators desiring the finest in chlorination control. For the first time, it is *possible to actually SEE what you're doing.*

WHAT THE RECORDER DOES: It provides a continuous, permanent record of actual chlorine residuals—either free available or total.

WHAT IT IS: The Recorder consists of a cell and a recording mechanism attractively housed in a handsome, gray enameled pedestal to complement any W&T Chlorinator installation. Optional accessories include a *Remote* Residual Indicator and a *Remote* Alarm System.

HOW THE RECORDER WORKS: In a continuous sample of the water under test, a function of the residual is measured and subsequently recorded on a 24 hour circular chart in terms of ppm of residual chlorine.



ADVANTAGES OF RESIDUAL RECORDING: Residual recording includes these big advantages—(1) Better chlorination control (2) A permanent record of performance (3) A check on operating irregularities (4) Determination of chlorine demand (5) To ascertain residuals in the distribution system (6) As a check on chlorine usage to avoid wastage, and (7) Because the record is continuous, operating data is available which could not be obtained by periodic testing.

WHAT USERS SAY: Many installations of this Recorder are in successful operation. Here's what some users say—

"—The recorder enables us to save many dollars on chlorine—"

"—This instrument functions with extreme accuracy and fidelity. It provides something that experienced water plant operators have long desired—"

"—I congratulate Wallace & Tiernan on the development of this useful equipment which is probably the most important advance in the science of chlorination in the last twenty years—"

Volume 39 April, 1949 Number 4

The Health Educator's Bookshelf*

GEORGE ROSEN, M.D., PH.D.

Director, Bureau of Public Health Education, Department of Health, New York, N. Y.

Books are to be called for and supplied on the assumption that the process of reading is not a half-sleep, but in the highest sense an exercise, a gymnastic struggle; that the reader is to do something for himself.—WALT WHITMAN

Those who have read of everything are thought to understand everything too; but it is not always so—reading furnishes the mind only with materials of knowledge; it is thinking that makes what is read ours.—JOHN LOCKE

MAY I begin by pointing out that the brevity of the title of this article is not to be taken as indicative of the length of the health educator's bookshelf. Despite William Hazlitt's diatribe "On the Ignorance of the Learned," most of us would agree certainly that the acquisition of knowledge through books does not make men ignorant. Indeed, others among us may even go further and with pleasurable recollection echo Petrarch's comment that each book "also suggests the name of others, and one begets the desire of the others."

Then, too, the problems that engage our attention change with time, and they change not at random but for the most part in relation to the altering demands of the world in which we live. If an article such as this had been prepared a generation or so ago its compass and emphases would in all probability have been quite different. And the contrast is greater still when we look at the "suggestions for forming sanitary libraries" appended to the *Shattuck Report* of 1850. Only some five or six of the titles listed can be credited to health education. Today the edifice of public health is so vast and so elaborate that in surveying the literature of health education we must of necessity content ourselves with exploring only selected chambers of this imposing structure.

Finally, it should be obvious that no matter what the field of endeavor the act of selection is a form of self-expression and therefore subject to those differences that arise from variations of personality. After all, if there were no difference of opinion, there would be no horse race. And so to the heart of the matter.

* Special Review Article prepared at the request of the Editorial Board.

STAPLE FARE AND BASIC BOOKS

A bookshelf like a diet should be well balanced. To carry the dietary analogy somewhat further, the bookshelf should have a group of books that, in a sense, will be its "basic seven." Or if the reader prefers an Oslerian approach, this basic group may be considered a *Bibliotheca Prima*. These are the books to which the health educator may turn for standard knowledge and not be disappointed.

For the health educator a question of primary importance is: How can the health worker get the desired message over to the public? The answer, more than likely, is to be found in Ira V. Hiscock: *Ways to Community Health Organization* (3rd ed.), New York, Commonwealth Fund, 1939. This practical volume based on the experience of a number of official and voluntary health agencies, both urban and rural, in various parts of the country offers devices and techniques that have proved effective in teaching the public to understand community health problems. It is profusely illustrated with actual materials. A good alternative selection which is also eminently practical in approach is W. W. Bauer and T. G. Hull: *Health Education of the Public* (2nd ed.), Philadelphia, Saunders, 1942. This volume is likewise well illustrated.

In the field of public health it is now recognized that no matter how adequate the programs of official agencies may be, these must go hand in hand with the organized effort of the community. There is no standard pattern that can be offered to all communities, but some ways in which programs can be developed may be seen in *Community Organization for Health Education*. The report of a committee of the Public Health Education Section and the Health Officers Section of the American Public Health Association, Cambridge, Mass., Technology Press, 1941.

This brings us naturally to the subject of what is needed by any community in the way of public health organization. Here the health educator may turn to any one of several excellent guides. Based upon more than two decades of experience as a health officer and teacher, Harry S. Mustard has prepared a number of books on this topic. *An Introduction to Public Health* (2nd ed.), New York, Macmillan, 1944, offers an instructive and pleasant presentation. The same author's *Government in Public Health*, New York, Commonwealth Fund, 1945, is a concise guide to the development and present state of public health organization in the United States, and effectively supplements the volume previously mentioned. An alternative choice which offers a more detailed presentation is Wilson G. Smillie: *Public Health Administration in the United States* (3rd ed.), New York, Macmillan, 1947. Finally, still another standard handbook of public health organization and practice is that edited by Ira V. Hiscock: *Community Health Organization* (3rd ed.), New York, Commonwealth Fund, 1939. A fourth edition scheduled to appear in 1949 is now in preparation.

In part, at least, it is the health educator's purpose to *inform* individuals and groups about the promotion of health and the prevention of disease. To do so, the educator must have available sources of information that are reliable. First and foremost as a standard work is the encyclopedic volume by Milton J. Rosenau: *Preventive Medicine and Hygiene* (6th ed), New York, Appleton-Century, 1935. With it, the health educator should have one good medical text, for instance, Henry A. Christian: *Osler's Principles and Practice of Medicine* (16th ed.), New York, Appleton-Century, 1947, or Russell L. Cecil: *Textbook of Medicine* (7th ed.), Philadelphia, Saunders, 1947. For in-

formation on infancy and childhood, Holt's *Diseases of Infancy and Childhood* (11th ed.), New York, Appleton-Century, 1939, is a standard reference. Two publications will, in most instances, supply whatever guidance is needed on communicable diseases. These are *The Control of Communicable Diseases,* an Official Report of the American Public Health Association (6th ed.), New York, A.P.H.A., 1945 (now being revised), and Gaylord W. Anderson and Margaret Arnstein: *Communicable Disease Control* (2nd ed.), New York, Macmillan, 1948.

MIND, BEHAVIOR AND HEALTH

If the health educator's job were only to inform people, an adequate performance could be achieved with the books mentioned above. But health education is more than just a matter of informing individuals or groups of people; it must be concerned equally if not more with motivating them. Until recently, health education was characterized alone by an eager didactic impulse to make the results of medical knowledge available to the public, to enlighten the people in matters of health and hygiene. Basic to these efforts was an explicit or implicit acceptance of the supreme social value of intelligence, and a realization that social intelligence could be made effective only if there was an informed public opinion. This standpoint derived from the enlightenment of the 18th century and was based upon an associationist, rationalistic psychology.

But even the 18th century was aware that man did not act by reason alone. Voltaire, for instance, characterized as insane the "idea of becoming wholly reasonable." With the rise of dynamic psychologies and the development of the social sciences in our century, the basis of health education could not remain unaffected. An increasing realization that the perceptions, in terms of which people act, reach their consciousness through the dark waters of their emotions and beliefs, will gradually lead to a reorientation of health education.

In approaching the question: What makes people act as they do? the health educator will do well to have on the bookshelf the writings of Sigmund Freud and Adolf Meyer. Selections from the works of these *Altmeister* of dynamic psychology are now readily accessible in *The Basic Writings of Sigmund Freud,* New York, Modern Library, 1938, and *The Commonsense Psychiatry of Dr. Adolf Meyer,* New York, McGraw-Hill, 1948. With these may be read Arnold Gesell: *The Embryology of Behavior,* New York, Harper, 1945, where an effort is made to deal from the viewpoint of embryology with that most complex of all action systems, namely, human behavior.

Recently the achievements of the social sciences during the war have begun to appear in book form. The first of these reports, a landmark in the history of applied social science, is Alexander H. Leighton's *The Governing of Men,* Princeton, Princeton University Press, 1945. Dr. Leighton, a psychiatrist who had studied Navajo and Eskimo societies, was sent in June, 1942, to the Relocation Camp for evacuated Japanese at Poston, Ariz., by the Office of Indian Affairs, which ran it. Two-thirds of Leighton's book chronicles the first year of life at Poston from the point of view of the applied social scientist. The remaining third of the book generalizes the experiences at Poston. In numbered principles and recommendations the author gives what seem to be the most effective ways of dealing with groups of people living under stress. It seems almost obvious that these recommendations should be applicable to all situations requiring the organization of people. While human relations do not lend themselves

to precise blueprinting, this is *must* reading for health educators.

Another focus of interest in the social sciences which has particular relevance for health education is the *small group.* The most important studies of group structure with many implications for the future development of education have been conducted by the late Kurt Lewin and his associates. These studies show uncommon sensitivity in the interconnections between individual behavior and group structure. A collection of papers issued under the title *Resolving Social Conflicts,* New York, Harper, 1948, will serve the health educator as a convenient sourcebook in Lewin's social psychology. While at the Massachusetts Institute of Technology, Lewin established the Research Center for Group Dynamics, which he conceived as a laboratory to develop a combination of research and application in action. For current ongoing investigation in this field, see the journal *Human Relations* (published by the Research Center for Group Dynamics, Cambridge, Mass.). A pamphlet entitled *Two Lessons of Group Dynamics,* published by Educator's Washington Dispatch, Washington, D. C., indicates an immediate practical application of results from this field of investigation. It is likewise worth noting that a series of bulletins on group dynamics is being published by the N.E.A. Department of Adult Education, 1201 Sixteenth Street, Washington 6, D. C.

Important developments have occurred in the analysis of communication and the formation of public opinion. As communication analysis moves in the only direction which will interest the health educator, namely, the study of the effects of communication on behavior, it will be necessary for the health educator to be aware of the pertinent literature in this field. Promising results have already been obtained in Robert K. Merton's *Mass Persuasion,* New York, Harper, 1946. The most valuable synthesis of the various methods of public opinion analysis has been produced by Paul Lazarsfeld, B. Berelson, and H. Gaudet in *The People's Choice,* New York, Duell, Sloan & Pearce, 1946. Two important phenomena uncovered by this study were the effectiveness of the small group as over against mass media, and the significant role of the opinion leader, namely, the person who influences opinion in direct personal contacts. Another important study dealing with the nature and significance of the informal group in factories and the emergence of "natural leaders" is F. L. Roethlisberger and W. L. Dickson: *Management and the Worker,* Cambridge, Mass., Harvard University Press, 1938.

Two collaborative volumes surveying the problems of communication will be of interest to health educators. These are Lyman Bryson (editor): *The Communication of Ideas,* New York, Harper, 1948, and Wilbur Schramm (editor): *Communications in Modern Society,* Urbana, Ill., University of Illinois Press, 1948.

For a basic concept of communication the health educator would do well to read and study the work of a pioneer philosopher of communication, George H. Mead: *Mind, Self, Society,* Chicago, University of Chicago Press, 1934. This is not easy reading, but the result is worth the effort. In this connection the philosophically interested educator may wish also to read Sir Charles Sherrington's *Man on His Nature,* New York, Macmillan, 1941.

The relevance of the social group for education is illuminated by Allison Davis's *Social Class Influences Upon Learning,* Cambridge, Mass., Harvard University Press, 1948.

Finally, as a guide and reference work to the field of communication, the health educator will want to have on the bookshelf H. D. Lasswell, R. D. Casey, and

B. L. Smith: *Propaganda and Promotional Activities. An Annotated Bibliography,* Minneapolis, University of Minnesota Press, 1935, and B. L. Smith, H. D. Lasswell, and R. D. Casey: *Propaganda, Communication and Public Opinion. A Comprehensive Reference Guide,* Princeton, Princeton University Press, 1946.

The effects on health education of advances in the social sciences are still meager, but there are indications that the impact is already beginning to make itself felt. Here too the needs of the war period exerted a facilitative influence. Food had to be rationed and so the problem of food habits was tackled. *The Problem of Changing Food Habits. Report of the Committee on Food Habits, 1941–1943* (Bull. Nat. Res. Council No. 108), Washington, D. C., National Research Council, 1943, presents some of the work that was done in this field and is required reading for every health educator. A second significant publication is *Motivation in Health Education. The 1947 Health Education Conference of the New York Academy of Medicine,* New York, Columbia University Press, 1948. From the four papers contained in this small book it is clear that we will not have an effective theory of health education until it is recognized that for the most part people use intelligence to attain ends dictated by feeling and conviction and not as a matter of rational motivation, and that more often than not this is the situation with respect to health.

THE TOOLS OF HEALTH EDUCATION

In the preceding section we have dealt with ideas and concepts, or more generally with theory relevant to health education. But theory without practice is of little earthly use, and so we shall now consider the tools of the health educator.

First come such works of reference as an unabridged Webster's *Dictionary,* or some other, such as the new *American College Dictionary;* Dorland's *American Illustrated Medical Dictionary* (21st ed.), Philadelphia, Saunders, 1947; *The World Almanac* for 1949; and an encyclopedia. If there is room and money for the *Encyclopedia Brittanica,* well and good. If not, the one-volume *Columbia Encyclopedia,* New York, Columbia University Press, will be found exceedingly useful.

For the literary side of the health educator's endeavors *A Manual of Style,* Chicago, University of Chicago Press, 1937 (8th impression, 1945), is essential. It helps in the preparation of printed or written materials and is a standard working tool in proofreading and editing. In addition, for those who apply something more than just the tape measure of utility, I should like to recommend a volume that has been for me both profitable and amusing, namely, Robert Graves and Alan Hodge: *The Reader Over Your Shoulder. A Handbook for Writers of English Prose,* New York, Macmillan, 1944. Two items that may be of interest in this connection are Sir Clifford Allbutt: *Notes on the Composition of Scientific Papers,* London, Macmillan, 1925, and G. H. F. Nuttall: *Notes on the Preparation of Papers for Publication in The Journal of Hygiene and Parasitology,* Cambridge, at the University Press, 1940. Particularly for biological and medical terms the health educator will find it helpful to have E. C. Jaeger: *A Source-Book of Biological Names and Terms,* Springfield, Ill., Thomas, 1944.

The proper handling of publicity and public relations requires guidance. Jack Ramsberger: *How To Make Publicity Work,* New York, Reynal & Hitchcock, 1948, is a good introduction to publicity methods. Although written specifically for nurses, the *A.N.A. Public Relations Workshop,* New York, American Nurses Association, 1948, a

practical manual of public relations techniques, will be found useful for a wider audience. Brief and breezy, *About Public Relations, Publicity* is an excellent orientation manual on these subjects. Prepared by the Public Information Unit of the New York City Health Department, it will be of interest to all health educators. A good discussion of policies and techniques involved in presenting news to the public is offered in *Publicity in New York City,* a special issue of *Better Times,* a social work weekly. (This is available from the New York City Welfare Council, 44 East 23rd Street, New York 10.)

For the preparation of annual reports, a copy of B. K. Tolleris: *Annual Reports—How To Plan and Write Them,* New York, National Publicity Council (130 East 22nd St., New York 10), 1946, will guide the tyro. With this, it will be useful to have on hand Rudolph Flesch: *The Art of Plain Talk,* New York, Harper, 1946.

Intelligent use of radio and film is important to the success of health education programs. A good introduction to radio is offered by Erik Barnouw: *Handbook of Radio Writing,* Boston, Heath, 1948. The value of films makes it necessary for the health educator to know about the sources from which health films can be obtained. The Educational Film Library Association, 1600 Broadway, New York 19, publishes a *Health Film Catalog* which lists and analyzes about 250 films, indicating their sources. Then there is the Library of Congress *Guide to United States Government Motion Pictures,* 1947, which also contains health materials. The National Film Board of Canada publishes a *Public Health Film Survey* which includes about 130 health films and another survey for approximately 300 medical films. These surveys may be obtained from the National Film Society, 172 Willington Street, Ottawa, Canada. In addition, various other organizations have larger or smaller catalogs. For example, the Health and Welfare Division of the Metropolitan Life Insurance Company, 1 Madison Avenue, New York, has brought out a *Catalog of Films on Health and Safety,* listing films and film strips which this organization produces and distributes. See also the Bibliography of Public Health Motion Pictures and Film Strips. *A.J.P.H.,* February, 1949, page 236.

The television field is still wide open, but the health educator ought to have at least one volume on the desk, and this might well be Hayland Bettinger: *Television Techniques.* Edgar Dale: *Audio-Visual Methods in Teaching,* is also recommended for its field.

Art techniques will, from time to time, be of interest to the health educator. One of the best bibliographies to this field is contained in *Parergon Supplement,* Evansville, Ind., Mead Johnson & Co., 1946. Should a single reference volume be desired, Ralph Mayer: *The Artists' Handbook of Materials and Techniques,* New York, Viking Press, 1943, may be recommended.

A volume by a master typographer which will be found very useful is W. A. Dwiggins: *Layout in Advertising,* New York, Harper, 1928. A new edition has been in preparation and will shortly be available.

For general reference, the bookshelf should have the *How-To-Do-It Series on Publicity and Public Relations Techniques,* National Publicity Council, 130 East 22nd Street, New York 10. Equally useful is the *Publicity Directory,* 1947, Special Issue of *Channels,* National Publicity Council for Health and Welfare Services, New York.

Finally, as an example of how techniques are put to work, one should have H. C. Baker and M. S. Routzahn: *How To Interpret Social Welfare,* New York, Russell Sage Foundation, 1947.

BOOKS FOR SPECIAL FIELDS

The impossibility of becoming omniscient makes it imperative that the health educator have on the bookshelf a number of books to which one can turn for rapid orientation. These should include at least the following: H. D. Pope and A. S. Chadwick: *The Modern Attack on Tuberculosis* (rev. ed.), New York, Commonwealth Fund, 1946; R. A. Vonderlehr and J. R. Heller, Jr.: *The Control of Venereal Disease,* New York, Reynal and Hitchcock, 1946; W. M. Gafafer (editor): *Manual of Industrial Hygiene,* Philadelphia, Saunders, 1943; and *Manual of Public Health Nursing* (3rd ed.), New York, Macmillan, 1939. As a guide to child care, Benjamin Spock: *Pocket Book of Baby and Child Care,* New York, Pocket Books, 1946, is cheap and has a down-to-earth viewpoint. One of the most practical guides for the first two years of life is *New York City's Baby Book. A Handbook for Parents,* New York, Department of Health, 1947. The three publications of the Children's Bureau, *Infant Care, Your Child from One to Six,* and *Your Child from Six to Twelve,* are similarly comprehensive and authoritative and ought to be readily available. Should the health educator need information on public health law, the book to consult, of course, is J. A. Tobey: *Public Health Law* (3rd ed.), New York, Commonwealth Fund, 1947. In the area of environmental sanitation, two volumes will give aid and comfort in time of need—H. S. Adams: *Milk and Food Sanitation Practice,* New York, Commonwealth Fund, 1947, and V. M. Ehlers and E. W. Steel: *Municipal and Rural Sanitation,* New York, McGraw-Hill, 1943. When vital statistics are required, two items will fill the bill in most respects. For the first four decades of the century the volume by F. E. Linder and R. D. Grove: *Vital Statistics Rates in the United States, 1900–1940,* Washington, D. C., Government Printing Office, 1943, and the *Physicians' Handbook on Birth and Death Registration* (9th ed.), Washington, D. C., Census Bureau, 1943, are most useful. Among the newer trends in the medical and public health fields, the background and objectives of social medicine are well presented in the collaborative volume *Social Medicine: Its Derivations and Objectives,* New York, Commonwealth Fund, 1949. In the area of rural health an excellent contribution has appeared, namely, F. D. Mott and M. I. Roemer: *Rural Health and Medical Care,* New York, McGraw-Hill, 1948; and for information in the dental field the health educator can now turn to Wisan and Pelton: *Dentistry in Public Health,* Philadelphia, Saunders, 1949. There is already an enormous literature on medical care so that no single volume alone suffices. Nevertheless the health educator as a citizen and by the very nature of his field of activity should be acquainted with the basic problems. A very useful statistical reference work is H. Hollingsworth, M. C. Klem, and A. M. Baney: *Medical Care and Costs in Relation to Family Income, A Statistical Source Book,* Federal Security Agency, Social Security Administration, Bureau Memorandum No. 51 (2nd ed.), 1947. A good recent effort to present the development and present state of public medical services is Franz Goldman: *Public Medical Care—Principles and Problems,* New York, Columbia University Press, 1945. See also his *Voluntary Medical Care Insurance in the United States,* New York, Columbia University Press, 1948. The New York Academy of Medicine report, *Medicine in the Changing Order,* New York, Commonwealth Fund, 1947, is another volume worth reading. The best statement of the fundamental issues involved in the medical care discussion is, in my opinion, still that of Walton H. Hamilton in *Medical Care for the American People.*

The Final Report of the Committee on the Costs of Medical Care, Chicago, University of Chicago Press, 1932. C. T. Brues: *Insects and Human Welfare* (rev. ed.), Cambridge, Mass., Harvard University Press, 1947, gives a satisfactory basic account of the public health aspects of insect-borne diseases. Unfortunately a day has only twenty-four hours, so that books which survey the highlights of a particular field and thus save time deserve a debt of gratitude, particularly when they are well done. A volume of this kind, which has been appearing since 1943, is the *Health Instruction Yearbook* compiled by Oliver E. Byrd, Stanford, Calif., Stanford University Press. The most recent issue is that for 1948. A similarly useful British volume is Baron Horder (editor): *Health and Social Welfare, 1947,* London, Todd Publishing Company, Ltd.

PERIODICALS ON THE BOOKSHELF

Current periodicals are an absolute necessity in order to keep abreast of any field of public health. For the health educator the *American Journal of Public Health, Hygeia, Science News Letter, Channels, Public Health Economics,* and *Public Opinion Quarterly* represent a minimum selection. Special needs may require other periodicals, perhaps *Population Index, Public Health Reports, Public Health Nursing, Bulletin of the National Tuberculosis Association, Cancer News* of the American Cancer Society, the *Industrial Hygiene Newsletter* of the U. S. Public Health Service, as well as its *Venereal Disease Information,* or *The Child* published by the Children's Bureau. The publications of various municipal and state health departments will be of interest at some time or other. *The Statistical Bulletin* issued by the Metropolitan Life Insurance Company is a useful source of information, as are also the *Tuberculosis Abstracts* of the National Tuberculosis Association. House organs and other publications of pharmaceutical houses will also be found to have items of health education interest. While not itself a periodical, the 35 year *Index of the American Journal of Public Health, 1911–1945,* Garrard Press, 1947, is a necessity. Finally, the health educator should be aware of *Tone,* the newsletter of the Cleveland Health Museum.

HISTORY, HUMANISM AND PUBLIC HEALTH

Public health is a field of human activity which owes its existence to the social and biological nature of man. A gregarious instinct and need for protection undoubtedly encouraged men to join together and live in communities. But man is also a biological organism and as such subject to biological needs and processes that are attributes of life. With the satisfaction of these needs (nutrition, reproduction, shelter) and the manifestations of these processes (health and disease) the community has had to reckon throughout known history. These efforts of the past have all entered, in some fashion or other, into the broad stream of modern public health. For the health educator to understand how the present has evolved from the past, and to be aware of the position of the public health worker in our complex society, a knowledge of history is essential. As the late Justice Holmes once said, "Continuity with the past is a necessity, not a duty."

The health educator should have at least one general history of medicine on the bookshelf. Several one-volume histories are available, but my personal preference is for Arturo Castiglioni: *A History of Medicine* (2nd ed.), New York, Alfred A. Knopf, 1947. If available, Fielding H. Garrison: *An Introduction to the History of Medicine* (4th ed.), Philadelphia, Saunders, 1929, should, of course, be consulted. However, Garrison is out of print, and the

prices of second-hand bookdealers are excessively high, so don't buy it unless you are a collector or especially interested in medical history. Furthermore, the health educator ought to be aware that no history is completely free of error; for specific points it is well to check several historians or to return to the original source, if it is accessible.

Either of these volumes should be flanked by Henry E. Sigerist: *Civilization and Disease,* Ithaca, N. Y., Cornell University Press, 1943, a book which offers a fascinating panoramic view by a master historian, and R. H. Shryock: *The Development of Modern Medicine,* New York, Knopf, 1947, which undertakes to portray the rise of modern medicine and public health against the background of intellectual and social history in general. A useful supplement to Shryock, presented with the accuracy and clarity characteristic of the author is Iago Galdston: *Progress in Medicine,* New York, Knopf, 1940.

Turning more specifically to the history of public health, one must be honest and say that while several books can be suggested there is no single volume offering a competent historical account of public health. There are of course the two volumes by Sir Arthur Newsholme: *Evolution of Preventive Medicine,* Baltimore, Williams & Wilkins, 1927, and *The Story of Modern Preventive Medicine,* Baltimore, Williams & Wilkins, 1929, but with all due respect to Newsholme as a health officer, teacher, and thinker, as a historian his approach is primitive. History ought to be a recreation of the changes exhibited in time and space of certain forms of human behavior, with some indication of the web of interconnection which binds together different facts and various lines of development. Nevertheless, as sources of factual data, the Newsholme volumes have a limited usefulness.

For the reader who wishes a history of sanitation that can be read with *pleasure,* I unreservedly recommend Reginald Reynolds: *Cleanliness and Godliness,* New York, Doubleday, 1946. Reynolds offers complete coverage from the water closets of Crete and Mohenjo-Daro to the latest developments of modern sanitary engineering, all in vivid, urbane prose.

The historical side of health education, with particular reference to health museums, is presented by Bruno Gebhard: "From Medicine Show to Health Museum, *Ciba Symposia,* March, 1947. Parenthetically, the health educator will find much of interest in the various issues of *Ciba Symposia* (published by Ciba Pharmaceutical Products, Summit, N. J.), now in its tenth year.

Public health administration and epidemiology have been well served by C.-E. A. Winslow whose *Evolution and Significance of the Modern Public Health Campaign,* New Haven, Conn., Yale University Press, 1923, and *Conquest of Epidemic Disease,* Princeton, Princeton University Press, 1943, deserve a place on the bookshelf where they may easily be reached.

The history of public health in America is still to be written, but meanwhile M. P. Ravenel (editor): *A Half Century of Public Health,* New York, American Public Health Association, 1921, serves to orient one.

The history of occupational hygiene has been a neglected field, but within recent years historical accounts of this field have begun to appear. Ludwig Teleky: *History of Factory and Mine Hygiene,* New York, Columbia University Press, 1948, provides an adequate introduction. For the history of an occupational group whose lineage may be traced back in almost unbroken continuity to neolithic times, the health educator should see George Rosen: *The History of Miners' Diseases,* New York, Henry Schuman, 1943.

In 1939, Morris Cohen, the philosopher, noted in his diary: "How marvel-

ous it is to pick up an old book and feel that you are communicating with a man who has long passed away, that you are getting at his mind, his feelings, and way of expressing himself! " This sense of continuity with the past requires one or several classics of public health on the bookshelf. Most easily available, of course, are those recently reprinted. Among these are John Graunt: *Natural and Political Observations made upon the Bills of Mortality,* Baltimore, Johns Hopkins Press, 1939; Snow *On Cholera,* New York, Commonwealth Fund, 1936; William Budd: *Typhoid Fever,* New York, A.P.H.A., 1931; and the *Shattuck Report,* Cambridge, Mass., Harvard University Press, 1948. *Papers of Charles V. Chapin, M.D.,* New York, Commonwealth Fund, 1934, may be classed in the same group.

Reference to John Graunt in the preceding paragraph brings to mind Major Greenwood with whose writings every public health worker should be acquainted. In this connection his *Medical Statistics from Graunt to Farr,* Cambridge, at the University Press, 1948, and *Epidemics and Crowd Diseases,* New York, Macmillan, 1935, are recommended.

Many of the achievements of modern public health are brought home to us most vividly when we read the biography or autobiography of the person who made the contribution. A section of the health educator's bookshelf should therefore be reserved for biography. As an introductory volume comprising selections from autobiographies, the book prepared by the present writer in collaboration with B. Caspari-Rosen: *400 Years of a Doctor's Life,* New York, Henry Schuman, 1947, may be suggested. Outstanding public health biographies are C.-E. A. Winslow: *The Life of Hermann M. Biggs,* Philadelphia, Lea and Febiger, 1929; S. Josephine Baker: *Fighting for Life,* New York, Macmillan, 1939; Hans Zinsser: *As I Remember Him,* Boston, Little, Brown, 1940; Alice Hamilton: *Exploring the Dangerous Trades,* Boston, Little, Brown, 1943; Ronald Ross: *Memoirs,* London, John Murray, 1923; and Sir Arthur Newsholme: *Fifty Years in Public Health;* London, George Allen and Unwin, 1935. The interested reader will find others. For the autobiography of one of the fathers of public health see the " Biography of Dr. Johann Peter Frank—written by himself, *J. Hist. Med.* 3:11–46, 279–314, 1948.

Many are the rivulets that feed the stream of public health—history, science, literature, and the humanities—but unfortunately neither time nor space will permit us to trace the contribution of each to the literature of the health worker. In conclusion, I wish only to refer the health educator to certain modern books that have had a seminal influence on our views of human behavior and culture. Among these I would include Ruth Benedict: *Patterns of Culture,* Boston, Houghton Mifflin, 1934 (there is also a cheap pocket edition); Lewis Mumford: *Technics and Civilization,* New York, Harcourt, Brace and Company, 1934; and *The Culture of Cities,* New York, Harcourt, Brace, 1938; Patrick Geddes: *Cities in Evolution,* London, 1915; Alfred N. Whitehead: *Science and the Modern World,* New York, Macmillan, 1925; and John Dewey: *Human Nature and Conduct,* New York, Henry Holt, 1922.

Last of all, when the day's work is done and one is ready for relaxed reflection, there is no better companion than *The Practical Cogitator,* an anthology of world literature ranging from the Old Testament to Gertrude Stein, selected and edited by C. P. Curtis, Jr., and Ferris Greenslet, Boston, Houghton Mifflin, 1945. To read this book is a liberal education, for the editors subscribe to that basic tenet of humanism, which should be the motto for the health educator—Nothing human is foreign to me.

Some Public Health Problems in Nuclear Fission Operations*

ARTHUR E. GORMAN, F.A.P.H.A., AND ABEL WOLMAN, DR. ENG., F.A.P.H.A.

Sanitary Engineer and Consultant, Atomic Energy Commission, Washington, D. C.

THE development and expansion of any new industry is and properly should be a matter of prime interest and concern to public health officials at all levels of government and across the entire spectrum of public health specialties. When this new industry holds promise of such profound importance to the national defense, economic future, and public health and welfare as does the atomic energy industry, it is clearly obvious that its problems, in so far as they may affect the public health, should be placed squarely before responsible and qualified officials in that profession for their information and for whatever assistance they may be able to give in meeting these situations.

The purpose of this paper is to discuss from the point of view of the public health engineer and the industrial hygienist certain problems of environmental and industrial sanitation which exist in this new industry; to tell what is being done to resolve them, and to indicate what we see ahead in atomic energy development which properly concerns these public health specialists and presents them with a challenge, as well as an opportunity to serve.

In discussing this new industry with professional public health workers, it is important to record at the outset that, in spite of all the unique features peculiar to production and research in nuclear fission operations, a rational approach to a study and solution of the public health problems presented still rests on well established principles in sanitary engineering and industrial hygiene. In this respect, therefore, the competent and experienced public health worker has much to offer in helping to guide this new industry. He need not assume that his interest, concern, and responsibility in its problems should await the day when the "mystery of the atom" is common knowledge or when he is invited to participate in resolving its environmental problems. On the other hand, as his experience with situations involving nuclear fission operations broadens, he will find he is dealing with a science which has a profound impact on his profession but concerning which his customary tools of measurement and appraisal are of little value.

The administrative health officer will recognize at once that he is dealing with an industry where young men predominate. He will see scientists using instruments and equipment which seem to challenge the imagination as to refinement in assembly, speed and accuracy of action. He will note that they control production units comparable in size with some of the facilities used at heavy industrial plants.

The epidemiologist will find that the

* Read before a joint Session of the Engineering, Public Health Nursing, and Industrial Hygiene Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

amount and period of radiation, instead of type and virulence of bacterial infections, are subjects of special significance and interest; the medical officer controlling the spread of communicable diseases will find his counterpart—the health physicist—insisting on proper shielding of personnel against radiation and decontamination of over-exposed areas; the bacteriologist will find ionization chambers and Geiger counters being used in place of culture media and incubators; the industrial hygienist will find a keen interest in determination of particle sizes in dust, primarily with respect to its radioactivity rather than with its chemical toxicity; the sanitary engineer will be intrigued by the number and size of the processing units which call for water supply, heat exchange, drainage, air conditioning and ventilation equipment; and he will want to know what becomes of the plant effluents and what, if any, contamination reaches the ground, the streams, and the atmosphere.

NATURE OF NUCLEAR FISSION OPERATIONS

To get back to the public health problems of the industry and an appraisal of them, perhaps a logical first step toward this objective would be to describe briefly nuclear fission operations as currently practised, since most people, even those in the technical professions, are not familiar with them, and relatively few have been able to visit the plants. In spite of its unique characteristics, the operations of this new industry follow a general pattern of other industries in many of its facilities and operating methods. As a consequence there is a definite parallelism in the problems it presents in waste disposal and environmental sanitation.

a. *Production*—Nuclear fission operations start as do other industrial operations with raw materials which must be refined. The principal one is uranium ore which must be crushed, sieved, and conditioned by a variety of processes before it is ready for exposure to neutron bombardment in a pile or reactor where new substances and energy resulting from nuclear fission are produced. In this preliminary processing, the usual problems exist in protecting workers from dust and fumes encountered in metallurgical and chemical industries. However, in this new industry exposure is more serious than in most industries because the natural ore is radioactive, although at relatively low levels. Some elements which must go into the structure of a pile call for various degrees of refinement and metallurgical operations, which involve hazards of dust and fumes.

The highly radioactive materials are produced after neutron bombardment of the prepared uranium in a "pile" or reactor. Here, as a result of nuclear fission, new products are created which are hazardous to handle because they emit particles of high energy which are damaging to living tissues. Operators must be shielded from these radiations, and this requires special design using abnormally thick lead and concrete walls.

The heat resulting from nuclear fission is tremendous and must of necessity be controlled, or considerable disintegration and possible destruction of the reactor structure itself would take place. In a reactor, this heat is dissipated by cooling, using air and water. These coolants, which are used in very large quantities, become radioactive. When they are disposed of they carry with them some radioactive waste products which are potentially hazardous and must therefore be subjected to special treatment.

After removal of the highly radioactive materials from a large production reactor, they must then be treated by various chemical and mechanical separations processes, common to many industries, to permit the particular ele-

ment which is to be produced—usually plutonium—to be obtained. Fission products which are also produced are recovered or stored depending on need for them.

A property of all radioactive substances is progressive decay through emission of energy. They may emit radioactive particles such as alphas, betas, and gamma radiations. Some idea of the rate of decay may be obtained from the fact that 1 gram of radium—equivalent to 1 curie—gives off 37 billion disintegrations per second.

The so-called half-life of a radioactive substance is the length of time required for one-half of its radioactive energy to decay. The half-life of radioactive elements may vary from a few seconds to a million years. Therefore, by a process of holding certain short half-life radioactive substances, the hazard of handling or exposure to them can be reduced. Provided its limitations are fully understood radiation decay through holding has preventive value. Its application might be compared to the health officers' use of quarantine for the period of incubation of a disease as a preventive measure.

As in other industrial chemical processes, there are wastes to be taken care of; and they too are highly radioactive. Those wastes which contain material of sufficient value for recovery are stored while those which, at the moment, have slight economic value are disposed of. Since all are radioactive and some highly toxic, the techniques of disposal must be carefully developed and constantly supervised.

b. *Research*—As contrasted with production plants in the atomic energy industry, there are many research laboratories. Some are small-scale units or production operated for development purposes. Others are for basic research and may handle only radioactive materials or isotopes produced at other plants and transported to these research centers. Since these materials are highly radioactive, great care must be taken in their handling and transportation, use and disposal; and the alert public health official has a responsibility to be sure that he is familiar with these operations and any potentialities which may exist by reason of them for exposure of the public or public facilities within the area of his jurisdiction.

c. *Radioisotopes*—As you may know the Atomic Energy Commission produces and sells radioactive isotopes of various kinds for use and research in medicine, biology, agriculture, and industry. In its *Fourth Semi-annual Report to the Congress,* the Commission lists 3,136 shipments of radioactive isotopes since July 1, 1946, distributed semiannually as follows:

DISTRIBUTION OF RADIOACTIVE ISOTOPES

	Number of Shipments
July 1 to Dec. 21, 1946	246
Jan. 1 to June 30, 1947	699
July 1 to Dec. 31, 1947	953
Jan. 1 to June 30, 1948	1,238
Total to June 30, 1948	3,136

From Oak Ridge, isotopes have been sent to users in 33 states, the District of Columbia, and Hawaii. Recipients were 236 institutions. By the end of June, 1948, 19 foreign nations had qualified to receive radioisotopes and to 15 of them a total of 159 shipments had been made.

Two isotopes — Phosphorus ^{32} and Iodine ^{131}—represent 2,024, or about 64.5 per cent of these shipments. Carbon ^{14} and Sodium ^{24} represent 367 shipments as an additional 10.5 per cent. Thus these four radioactive isotopes account for 75 per cent of the shipments made to date.

Classified by broad fields of professional application these isotope shipments were used as in Table 1.

The half-life of some of the more common isotopes currently used for research in medical, public health, industrial, and biological laboratories is listed (Table 2):

TABLE 1

Use in	Number of Shipments of Radioactive Isotopes July 1, 1946, to June 30, 1948
Medical Therapy	1,291
Animal Physiology	992
Chemistry	262
Physics	257
Plant Physiology	156
Industrial Research	90
Bacteriology	64
Metallurgy	20
Other	4
Total	3,136

TABLE 2

Element	Symbol	Mass No. of Isotope	Half Life
Carbon	C	14	5,100 yrs.
Zinc	Zn	65	280 days
Calcium	Ca	45	180 "
Sulphur	S	35	87.1 "
Iron	Fe	59	44 "
Phosphorus	P	32	14.3 "
Iodine	I	131	8.0 "
Copper	Cu	64	12.8 hrs.
Potassium	K	42	12.4 "

CONTROL MEASURES NECESSARY

The usual safety and public health control measures carried out by well managed industries and research institutions are not adequate for complete protection of persons and property in the production and use of nuclear fission materials. This is because of the new hazards introduced by radioactivity. It is a reason why those of us who have been accustomed to considering industrial and environmental problems in terms of chemical, bacterial, biological, and general physical properties must broaden the scope of our appraisal to include radioactivity. This calls for a better understanding of the principles of nuclear physics and familiarity with its technical terms, units, and standards, and also an ability to interpret them and to blend their values with others we are most accustomed to work with.

At plants operated under the Commission's control, measures for protection of working personnel against overexposure to radioactivity usually are carried out by skilled technicians called health physicists. They monitor working areas and see to it that any contamination which occurs is removed and properly disposed of. While their earlier attentions were directed principally to protection against radioactive contamination in-plant and on-site, more recently these specialists have given much consideration to the off-site problems involved when waste from nuclear fission operations for one reason or another are released to the atmosphere, into the ground, or on surface areas.

SANITARY ENGINEERING RESPONSIBILITIES

It is this environmental phase of the problem which is of special interest to the sanitary engineer and the industrial hygienist. Therefore, it is the one which we shall cover most fully in this paper. It is an area where the opportunity and challenge is the strongest and where, by reason of their education and training, the sanitary engineer and the industrial hygienist can be of special service. The sanitary engineer, the industrial hygienist, and the health physicist are indeed key men in the progress of this new industry. It has become almost axiomatic that an industry like a community can have a healthy growth only so long as it can adequately dispose of its own waste products. Because of nuclear fission we are actually on the threshold of a new era in industrial development; therefore, every public health worker should acquaint himself with the problems which this new industry will present, especially in disposal of its wastes.

The need of educating and training sanitary engineers and other public health specialists in nuclear physics and its applications in the expanding field of atomic energy is recognized by the Commission. A small group of sanitary engineers and chemists in federal agencies, other than the Commission, are being given training at Oak Ridge and Los Alamos; and it is planned to expand this activity to water and sewage

plant operators and public health officials. The need of extensive education and training of sanitary engineers and industrial hygienists in all categories of the profession and in private as well as public service in the elements and problems of this new industry is obvious. Programs designed to meet this need are under serious consideration; and, in the near future, a seminar will be held in Washington at which a selected group of key men, representing water and sewage works operators and state sanitary engineers, will be informed of current problems in the industry and will be requested to suggest effective ways of attack.

PROBLEMS OF WATER SUPPLY

Recognizing that the disposal of radioactive or toxic wastes from its plants or research operations in increasing quantities could create serious problems, the Atomic Energy Commission and its various area contractors have given and are continuing to give much consideration to reducing such contamination to an absolute minimum. But a water-cooled reactor requires a large volume of water for heat-exchange purpose, and this water must be disposed of. The type and degree of radioactivity in such water can be determined and controlled. Knowing the radioactive characteristics of the water leaving the reactor, the period of time it will continue to emit nuclear energy can be determined. Therefore, having knowledge of the amount of this energy in particles or radiations which the human system can tolerate with safety, it is possible to determine the extent of hazard involved in the disposal of such wastes.

As all radioactive substances undergo decay until they cease to emit energy, knowledge of the length of time required for this decay provides one method of appraising the extent of the problem. Consequently, retention is one method of treatment relied upon for cooling water which must be returned to streams. Unfortunately, some radioactive substances have long half-lives. In such cases, these substances must be removed from water used for cooling reactors unless their quantities are in such small amounts that, with dilution, the hazard of their presence is negligible. The technical control in treatment of water used for cooling nuclear reactors must be of the highest order. A healthy development of this industry would require application of the special skill and experience of the water works designers and specialists in water treatment.

At atomic energy plants, as well as those of other industries, there is always the remote possibility that an accident or a spill will occur with the result that the waste products in abnormal amounts might be released. Great care is taken to avoid such accidents, and provision is made for special treatment and use of standby equipment should they occur. Nevertheless, it should be the concern of every sanitary engineer responsible for water supplies in an area where nuclear fission products are produced or used to appraise and evaluate risks to such supplies under all circumstances. He should work out with operators of such plants a system of routine checks and emergency warnings so that at all times protection against radioactive contamination will be afforded. The Commission will coöperate fully with the U. S. Public Health Service in its research program with the states and industry to resolve any problem of stream pollution which may result from its operations.

The discharge of radioactive waste products into or onto the ground also has potentialities of contaminating water supplies; and, here again, long known principles of disposal of wastes from industrial plants apply. Radioactive waste products with long half-lives could create serious hazards, and their discharge deserves careful study and

effective control. Where such wastes are disposed of to the soil, it is of basic importance that information be obtained as to the rate of flow of the ground water and the dilution possibilities so that at all times the extent and degree of contamination may be known. Fortunately, some radioactive substances are known to attach themselves firmly to soil and do not travel far from the point of disposal in soil. As a result, they undergo decay in a localized area and spend their radioactive energy before they can be transported to more distant sources of water supply. But this favorable relationship should not be accepted as adequate protection under all circumstances. Common prudence dictates that the facts in each case should be obtained where sources of water supply might be involved.

There is evidence that such processes of water purification as coagulation and sedimentation and sand filtration are quite effective in removing some radioactive substances from water. The problems of disposal of the radioactive sludge and controlling the build-up of radioactivity in filter media are deserving of special consideration. These are being studied by the Atomic Energy Commission, and facilities for extending research of this kind are being installed at Oak Ridge and Los Alamos.

Radioactive particles carried into the atmosphere by gaseous effluents from nuclear fission operations could contaminate the air we breathe and, on settling, with or without rainfalls, contaminate the soil and vegetation on which they deposit. Thus watersheds and open reservoirs could become contaminated if the half-life of the radioactive product is long. Here again, the elements of time and dilution, as well as fixation, are factors of safety. But an alert and responsible sanitary engineer should not accept these favorable influences as a substitute for determining the facts.

Still another aspect of radioactivity in water, interesting and significant to sanitary engineers and biologists, is evidence that such energy does not unfavorably affect many plankton growths, and is accumulated within these organisms. Algae and other forms are known to grow prolifically in water which is quite radioactive. The potentialities and significance of this finding are especially interesting and important to all interested in the biology of streams and their subsequent use as sources of industrial and public water supplies.

COMMUNITY WATER SUPPLIES

At Oak Ridge, Hanford, and Los Alamos, the Commission, through its contractors, operates communities, housing and serving about 60,000 persons, including employees and their families and, during period of expansion, construction camps for tens of thousands of temporary employees. The problem of supplying water to these areas has been much more involved than that of providing water for normal communities of the same size. This has been due partly to the fact that new communities had to be built hurriedly in remote areas and under difficult conditions.

At the Richland, Washington, Village, housing employees of the Hanford Works, the per capita consumption of water on hot days is about 1,100 gallons per day, over two-thirds of which is for sprinkling lawns and parkways. Currently, more than half of the water supplied to Los Alamos Village must be pumped on elevation of nearly 2,000 feet.

Private water works consulting engineers were employed to design these facilities, and have successfully resolved the problems involved.

PROBLEM OF WASTE DISPOSAL

Waste from nuclear fission plants as from most industries are liquid, dry, and gaseous. It is the policy of the Commission to develop ways and means of

treating wastes resulting from production and research activities at plants under its jurisdiction so that there will be no hazards to its employees or to others. Toward this end, special working groups of outside consultants are collaborating with staff employees in various areas of operation and at research institutions.

Liquid Wastes—Because of the scarcity of the raw material such as uranium ore and the value and importance of fission products resulting from the separations processing subsequent to bombardment in the reactors, great care is taken not to lose these products. This calls for on-site storage of large quantities of valuable and highly radioactive materials, especially at production plants. Waste products with little value but having radioactive or toxic properties must be disposed of. This poses a problem both of economics and of safety. Cribbing and lagooning, which are common practices in many industries, have been carried out with a fair measure of success, but it is recognized that such practices have potential hazards and limitations.

With the objective of maximum product recovery and minimum of radioactive waste to be disposed of, the Commission is seeking to develop processes which will in effect result in a closed system. One of the unique problems in the nuclear fission industry is that equipment and facilities which come in contact with highly radioactive contamination also become contaminated and, therefore, must be decontaminated or be disposed of. For this reason, use of many of the methods and much of the equipment common to other industries for treatment of industrial waste must be ruled out or modified because of the end problem of ultimate disposal. This need of developing equipment small in size and methods which will minimize human exposure is a complication which must be faced at all times in seeking practical solutions to problems of disposal of wastes in the field of nuclear fission.

The ability of certain natural soils and artificial media and resins to adsorb radioactive liquid wastes is a subject of much interest and research. The possibility of concentration of radioactivity by biological methods and, conversely, the effect of various amounts of radioactivity on biological processes common to sewage treatment are being studied.

There has been some concern on the part of operators of sewage treatment works that the disposal of waste resulting from the use of radioactive isotopes at hospitals and research institutions might have an adverse effect on the sensitive biological processes at these works. Their concern is wholly understandable and, currently, research programs are being initiated designed to obtain basic facts. The rapid increase in the use of radioactive isotopes in institutions and industry poses many other problems which call for answers such as the degree, if any, to which plumbing fixtures in buildings can become radioactive, and to what extent facilities in sewer systems, such as receiving basins, sump and booster pumps, will require monitoring before entered or handled by workmen.

Radioactivity is indeed a type of contamination to which the sanitary engineer and the industrial hygienist of the future will need to give serious consideration and which he must be able to measure and to interpret. Its potential as a contaminant in cases where interconnections between piping systems in buildings or institutions exist is as insidious as it is hazardous.

Dry Wastes—In the various processing stages, especially in metallurgy, dusts and chips of radioactive and, in some cases, toxic materials result. That which can be, is reclaimed. As a rule the remainder, if of a low level of radioactivity, is buried. If of high level, it is stored in a container—well shielded against radioactivity—for subsequent

burial when it is safe to do so in the ground, usually in the same container. Instruments, containers, glassware, and facilities used in handling radioactive materials become contaminated. They are decontaminated where this is possible or practical but ultimately they become radioactive to a degree where they must be condemned for further use. Again, depending on the degree of radioactivity, these activities are disposed of by burial either in shielded containers or direct. Incineration of radioactive materials is not advisable unless adequate facilities are available to remove all activity from the resulting gases, which in itself is not a simple task.

The entire problem of disposal of so-called dry wastes resulting from nuclear fission operations is receiving much attention. The usual salvage operations common to most industries cannot be resorted to and great care is taken to see that contaminated material having value is not released until it is safe to do so; and in the case of long-life radioactivity the facility is destroyed rather than risk possible re-use. As this industry expands, the temptation to reclaim value in contaminated material and equipment could introduce serious public health hazards which must be prevented.

Gaseous Wastes—Certain constituents of the air which are passed through an air-cooled reactor become radioactive. The concentration is low and the half-life short. Therefore, if operation is discontinued when atmospheric conditions are most unfavorable, it is possible by use of special air treatment equipment to meet with a high factor of safety permissible limit established for atmospheric contamination. As in most chemical processing — dry or in solution — very small particles in dust or mists are carried away through the ventilating systems. Those which are radioactive could create a hazard, especially if discharged to the atmosphere in such a way as subsequently to expose human beings or vegetation in amounts which would be injurious. Similarly, exhaust gases from hoods in experimental and research laboratories could, on a lesser scale, create local hazards. The Commission is keenly aware of this stack gas problem and has authorized the installation of most elaborate equipment for filtering and otherwise removing particles and gases from stack and hood effluents. In this field, as in that of liquid waste disposal, work is being pressed, under the direction of a special committee of consultants, looking forward ultimately to the complete removal of all gaseous wastes from Commission plants and the development of new or adaptation of existing gas-treating facilities for highly efficient operation under conditions singularly peculiar to this new industry.

TECHNIQUES AND TOLERANCE LIMITS

In any consideration of contamination, scientists are accustomed to make use of certain standards or permissible levels. Sanitary engineers and industrial hygienists already need some guides as to relative degrees of radioactive contamination, techniques for their measurements, and safe limits for public safety and health. The radiologist and the health physicist have done much to develop such techniques, standards, and equipment, and deserve much credit for their work along these lines. By means of instruments, such as electroscopes, Geiger counters, and ionization chambers, they evaluate the radioactive energy from nuclear particles, such as alpha and beta particles and gamma radiations. They have made much progress in developing instruments of increasing sensitivity and accuracy. More work along these lines has to be done before the public health profession has the tools it needs to work with. The sanitary engineer, the industrial hygienist, and the so-called health physicist have a lot in common and each has

much to give and receive of his knowledge and experience in the development of this branch of science.

Ultimately, permissible levels for radioactivity, developed and being used currently at plants under the Atomic Energy Commission, will have to be subjected to intensive review by outside experts of wide experience in medical and public health and safety research. They naturally will want all standards recommended to be supported by clinical, epidemiological, and biometric evidence before they are generally accepted. The history of the evolution of other technological standards, which have stood the test of time, forewarns us of this eventuality.

The current values were arrived at largely by mathematical calculations as to equivalent energies involved in different substances and relating these to experience in exposure of human beings and animals to radium. It is pertinent to say that as experience is gained, there is a definite trend in the atomic energy field toward stricter standards. The International Congress of Radiobiology in 1934 had set a limit at 200 milliroentgens (mr) per day, while the American Advisory Committee on X-ray and Radium in 1936 had set the figure as 100 mr per day for X and gamma radiation. Limits currently used stem from a tolerance level for total body exposure of 0.1 roentgen equivalent man (rem) in any 24 hour period. In the case of alpha emitters such as plutonium, the objective in establishing limits is to prevent deposition of a total of more than 1.0 microgram in the body during a person's life.

Morgan gives the permissible limits for 24 hour exposure of employees as established in the Oak Ridge National Laboratory and used by a number of other laboratories as follows:

100 (mr) for X and gamma radiation
100 (mrep) for beta radiation
10 (mrep) for alpha radiation
20 (mrep) for fast neutrons
50 (mrep) for thermal neutrons

Morgan makes the significant point that the factors of safety are low and that we should think of these figures as "maximum allowable" rather than "tolerance" amounts of radiation. In the same paper from which these data are taken he presents extended curves and tables summarizing values for tolerances over one year both in air and water. The values are tentative and much too detailed to be reproduced here in full, but a few figures are listed below as examples:

		One Year Tolerance Concentration			
		In Air		In Water	
Element	Assumed Effective Half-Life	microcuries per ml	micrograms per ml	microcuries per ml.	micrograms per. ml.
Ra^{226} pdts	2 wks	2×10^{-10}	2×10^{-10}		..
Ra^{226} pdts	10 yrs.		..	4.4×10^{-6}	4.4×10^{-6}
C^{14} (graphite)	2 mos.	1.2×10^{-7}	2.6×10^{-6}		..
Na^{24}	14.8 hrs	6.3×10^{-7}	7.1×10^{-11}	4.9×10^{-4}	5.5×10^{-11}
Ca^{45}	150 days	2.1×10^{-7}	1.3×10^{-11}	3.6×10^{-3}	2.2×10^{-7}
S^{35}	25 days	3.1×10^{-6}	7.3×10^{-11}	0.41	9.4×10^{-7}

EXAMPLES OF ATTACK

A great deal of excellent work has been carried out and is in progress or planned for resolving the problem of protecting man and his environment against radioactivity. Of special interest to sanitary engineers are the following:

Meteorology—At the Hanford Works, careful experiments have been carried out to determine the most favorable atmospheric conditions under which to carry out operations. Equipment for similar studies has been installed at the Brookhaven National Laboratory where perhaps the most extensive meteorologi-

cal program of all areas will be carried out. The U. S. Weather Bureau will assist in studies of atmospheric problems at most of the larger areas of operation. The selection of size for reactors and other facilities where radioactive materials are produced, stored, or experimented with, calls for very careful appraisal of meteorological factors, and this is in line with the Commission's policy.

Safety Manual—A manual of *Standard Safety Requirements* has been prepared containing information to be used by plant operators in protecting personnel and by designers in preparing plans for new and for revision of existing plants and facilities. Naturally, it has been subject to considerable revision and change as our experience indicates these needs.

Ground Water Protection—The U. S. Geological Survey is coöperating actively in studies and evaluation of surface and subsurface contamination of water supplies where radioactive and toxic wastes may be discharged into or onto the ground. Such problems are currently being given special consideration at the Hanford Works in Washington, Oak Ridge in Tennessee, and at the Brookhaven National Laboratory on Long Island.

Waste Disposal Research—Contracts have been let with several nationally known chemical engineering and development companies for research to improve chemical processing and recovery of valuable products from stored wastes and for reducing the volume and radioactivity of final plant wastes to the smallest amount practical. Coöperative programs with the Public Health Service and the Tennessee Valley Authority have been developed at Oak Ridge, with the Public Health Service at Los Alamos, and with New York University, for study of the effect of radioactivity on biological processes, especially those common in sewage treatment and stream pollution. Included in one or more of these programs will be studies of the effect of radioactive isotopes on various materials used in plumbing and sewers and related facilities. The cumulative effect of radioactivity on algae and various plankton forms and the effectiveness of standard water purification methods in removing radioactive contamination from water will be studied.

A program for studying the Columbia River in the vicinity of the Hanford Works is being developed with the Public Health Service. The construction of McNary Dam—miles downstream from these works—is expected to have a considerable effect on the biology of the river upstream from the dam, and it is desired to determine the effect of this dam and any relation this may have to operations at the Hanford Works.

USE OF SANITARY ENGINEERS

At most of the larger AEC areas, sanitary engineers are employed to assist in the solution of problems in water supply protection, waste disposal, and general environmental sanitation, including related problems in the villages where workers are housed. The Atomic Energy Commission recognizes the need of complete control over the various environmental factors which concern and affect this new and unique industry. It is most anxious that in its current operations and in the expansion which is sure to come, full advantage be taken of the experience of other new industries in order that their earlier difficulties may be avoided. Many of the areas of vulnerability in the atomic energy field which affect environmental sanitation are those in which the sanitary engineer is especially trained to help. As the industry grows, there will be an increasing need of assistance from sanitary engineers, both at atomic energy plants and in areas surrounding them.

When one considers the potentialities of wartime hazards involved in the field

of atomic energy, whether in production for military purposes or the possibility of enemy action, the importance to the national defense of having a large number of public health workers trained in ways and means of coping with hazards of nuclear fission products is evident to a sharp degree.

CONCLUSION

We should like to reëmphasize that (1) the continued expansion of the nuclear fission industry presents many problems and, therefore, an opportunity and a challenge for the trained sanitary engineer; (2) the Atomic Energy Commission is striving actively for a permanent solution of its waste disposal problem; (3) its objective is that this new industry may expand to meet its potentialities without creating objectionable or hazardous conditions at and in the vicinity of its plants as many new industries have done; (4) public health workers should be trained in fundamentals of nuclear physics so that they may have a better understanding of this new industry and its environmental problems; and (5) the need of training sanitary engineers is especially acute considering their responsibilities in a national defense program.

Public Health Degrees 1947-1948

The January, 1949, issue of the *American Journal of Public Health* carried the Report on Public Health Degrees and Certificates which has been compiled by the Committee on Professional Education annually for the past 15 years. As in previous years, the report on the academic year 1947–1948 contains valuable information on enrollment, the professional backgrounds of the students, the degrees offered and the degrees granted by the various universities. Because of the special concern which the Engineering Section Project has had in training of engineers and sanitarians, the material this year is more complete than previously with respect to the postgraduate degrees in sanitary and public health engineering; in addition the findings of a special study on undergraduate students and degrees in engineering and sanitation are included. Two summary tables only were published in the January *Journal*. A set of 10 additional detailed tabulations in multilith form are available free on request from the office of the Association.

Housing and Health

Sanitary Aspects of the Dwelling *

M. ALLEN POND, F.A.P.H.A.
Assistant Chief of Engineering Activities, U. S. Public Health Service, Washington, D. C.

DURING the past century "sanitary housing" has been the subject of numerous studies, endless discussion, and some legislation. The political significance of housing has increased with the expansion of public interest in human welfare. After World War I, efforts were made by the National Bureau of Standards and other agencies to influence local governmental units to strengthen building, plumbing, and fire prevention codes. The enactment in 1934 of legislation that established the Federal Housing Administration put the United States Government for the first time squarely in the struggle to improve housing standards and conditions. Three years later the Wagner Act was based on acceptance of the thesis that sanitary housing for all the people is essential to the national welfare, and that continuation of slums is not in the public interest.

Early and recent leaders in the public health movement also have concerned themselves with housing as a factor in community health. Here in Massachusetts a century ago Lemuel Shattuck pleaded for better housing for factory workers.[1] Stephen Smith, 15 years later, presented a strong case against slums and stressed the public health importance of decent housing.[2] In recent years, many of the more thoughtful figures in public health—Winslow, Wolman, Williams, Vaughan, to name a few—have repeatedly emphasized the significance of housing in the community health program.

No purpose would be served here by reviewing what is known about the epidemiological significance of slums and blighted areas. Anderson some years ago pointed out that the standards of housing rest on insecure epidemiological foundations,[3] and others have emphasized this. Nevertheless, whether the exact causal relationship between housing quality and health can be accurately measured, there is ample evidence that good housing is not incompatible with health.

SCOPE OF HOUSING SANITATION

The scope of housing sanitation is broad. Virtually no ordinary problem in environmental sanitation is missing from the realm of the hygiene of housing, and there are problems in housing that are new, if not obscure, in health department practice. To the usual problems may be added those relating to functional design, materials of construction, noise control, illumination, aerobiology, and environmental hazards to mental and emotional health.

Not only is the field broad; it is also complex. It involves legal, economic, and sociological considerations as well as public health. There is a long history of governmental regulation of housing through the use of sanctions to control the structural aspects of new buildings.

* Presented before the Conference of Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

Regulation of occupied multifamily housing has been common for nearly a century. Yet there has been surprisingly little cross-fertilization of the professions and trades concerned with the building, marketing, and control of housing.

Although existing public health activities relate to many of the technical problems in housing, the field itself has been the subject of few specific local health programs. Because housing problems are so complex, it is necessary that there be a frontal attack on them.

Furthermore, it happens that the dwelling is the principal environment of man. Infants average 22–24 hours per day, housewives 20–22, school children 20, and wage earners 15–18 hours daily at home. On the basis of lengths of exposure to hazards that are common to the factory, the classroom, and the dwelling, it is evident that the home is far more significant than either the work place or the school. Gross evidence to support this generalization is to be found in morbidity and mortality data for home accidents, in analyses of the principal causes of industrial absenteeism, and in studies of the spread of epidemic childhood diseases among the younger siblings of school children. We need not and should not wait for more exact data before beginning to act.

STANDARDS

Wide varieties of standards for sanitary housing have been recommended by federal agencies and national associations. In rural and suburban areas especially, Federal Housing Administration standards for dwellings built with guaranteed mortgages have been significant in developing codes of practice where building regulations were formerly either nonexistent or inadequate and poorly enforced. F.H.A. standards deal not only with water supply and sewage disposal but also with heating, fire resistance, structural safety, and minimal room sizes. It is probable that these standards have had greater impact on housing quality the country over than any others.

In the United States the regulation of new housing has traditionally been a function of building officials whose primary concern has been with structural safety, prevention of fire, and protection of life and limb against the hazards of structural collapse or conflagration. In a comparatively narrow sense, building regulations have had sanitary significance in that they contain elemental requirements relating to water supply and sewage disposal, heating, lighting, and ventilation. With rare exceptions, they have been arbitrary, inflexible, and essentially unimaginative, and modern slums have been produced in the face of them.

The control of the quality of occupied housing is usually a responsibility of local health departments. In areas where there are no effective, full-time local health units, there is practically no official action to preserve the quality of good housing, and to improve slum and blighted dwellings. This is understandable. It is not so easy to explain the failure of otherwise effective local health agencies to carry out incisive housing sanitation programs. The leadership of health departments in Memphis, Baltimore, Milwaukee, Los Angeles, St. Louis, and a handful of other communities is noteworthy because it has begun to do something more than investigate housing complaints.

Some of the delay in health department action to improve housing quality may be ascribed to a lack of standards. Health officials have tended to resist activities that are not based on cause and effect relationships. It is obvious from our earlier consideration that such relationships have not been demonstrated in the hygiene of housing, and standards of housing quality have perforce been based on group judgment rather than precise knowledge.

The Committee on the Hygiene of Housing during the past two years has undertaken the preparation of standards for the neighborhood environment, structures and dwelling units, and equipment which is used in the home. Many of the standards recommended by the committee are the product of the considered judgment of its members. The range of training and experience of this group is so wide as to make their group opinions, if not valid, at least cogent.

BASIC DEFICIENCIES

The Committee on the Hygiene of Housing considers that each of the following conditions represents a basic deficiency in the quality of a dwelling:

1. Contaminated water supply
2. Water supply outside unit or structure
3. Toilet shared or outside the structure
4. Bath shared or outside the structure
5. Crowding of more than 1.5 persons per habitable room
6. Crowding of sleeping rooms (persons = 2 x number of sleeping rooms + 2)
7. Less than 40 sq. ft. of sleeping area per person
8. Lack of dual egress
9. Installed heating lacking in three-quarters of rooms
10. Lack of installed electricity
11. Rooms lacking window
12. Serious deterioration

Any dwelling containing 4 or more basic deficiencies is considered to represent an extreme slum.[4]

In surveys recently made in Atlanta, Los Angeles, and Milwaukee, the median numbers of basic deficiencies were found to be 4, 2, and 1, respectively. The high incidence of basic deficiencies in the Atlanta study doubtless stems from the fact that the surveyed area of 2,292 dwelling units represents a known slum. However, there were 4 or more basic deficiencies in 15 per cent of the dwelling units in a representative Los Angeles survey district, and 3 or more basic deficiencies were found in 2,100 of the 9,489 Milwaukee structures appraised.

There are at present no nation-wide data on the incidence of basic deficiencies in either urban or rural housing units. Facts gathered by the Bureau of the Census in its sample survey of April, 1947, however, indicate that there are at least 4.1 million units in need of major repairs (i.e., seriously deteriorated), and 11 million additional units lacking private baths and toilets.[5] Analysis of the available data indicates that there are at least 1.9 million non-farm homes in the United States that have 3 or more basic deficiencies. Nearly 2.5 million dwellings are sheltering more than 1.5 persons per room. Almost one-sixth of all non-farm, non-white units, and 1 in 10 farm houses are thus overcrowded.

Rural housing tends to have the most obvious sanitary defects. In 1940, for instance, there were 3 essentially rural states in each of which more than 100,000 dwellings lacked a source of water supply within 50 ft. of the house, 10 other states each had between 50,000 and 100,000 homes in the same category, and 26 additional states had between 10,000 and 50,000 dwellings with the same deficiency. In North Dakota 29.5 per cent (47,430) of all homes lacked a water supply within 50 ft. of the house. Even urbanized Connecticut had 1,641 such units. Furthermore, sanitary surveys and laboratory sampling programs in several states have shown that more than 75 per cent of existing farm water supplies are unsafe.

In general, more dwellings are provided with sewage disposal facilities than with conveniently accessible water supplies. No state reported more than 100,000 units without toilets or privies, and only North Carolina reported more dwellings lacking sewage disposal facilities than homes without water supplies within 50 ft. The privy building programs that were common between 1934 and 1940 seem to have made an obvious dent housingwise as well as epidemiologically. Unfortunately, surveys sponsored by state health departments since

the end of World War II indicate that more than three-quarters of existing privies are still insanitary.

These specific deficiencies are not limited to rural homes. In the metropolitan areas of New York, Baltimore, Detroit, Chicago, St. Louis, and Los Angeles, the 1940 census revealed 15,709 dwellings lacking water within 50 ft. of the structure. The same communities had 11,795 homes without toilets or privies. In 1945, 12 per cent of all non-farm units in the nation lacked running water. Is this not evidence that there are tangible housing sanitation problems that merit health department action?

THE NEIGHBORHOOD

The dwelling and structure are not the only components of housing that have health significance. Board and Dunsmore have described some of the sanitation problems of urban fringe areas,[6] and the experience of the federal housing agencies demonstrates the health importance of site selection and community planning. Furthermore, the Committee on the Hygiene of Housing has considered the neighborhood as a basic planning unit, and has published standards on the subject.[7]

The significant health principles that should be met in an adequate community environment are:

1. Protection against accident and communicable disease hazards, including provision for maintaining cleanliness
2. Provision of adequate daylight, sunshine, and ventilation with non-polluted air
3. Protection against excessive noise
4. Protection from fatigue and provision of reasonable privacy for the family
5. Provision of opportunities for normal family and community life in esthetically satisfactory surroundings protected against moral hazards

More and more it is recognized that the effect of substandard environment extends beyond direct threats to physiological health, and that it involves also significant detriments to mental and emotional well-being. For the present, at least, measurement of the total health significance of neighborhood deficiencies appears to be impossible. It is to be expected, however, that, like the Mosaic laws, these current beliefs of thoughtful men will some day be validated.

FUTURE PROBLEMS

Events of the past decade have cast a shadow upon the future of urbanization. Great centers of population have become the targets of combatant nations, and civilians in possible future wars will share the horrors which traditionally have been the lot of warriors. A recent release of the National Security Resources Board, in addition to describing some of the factors relating to industrial relocation, contains this statement: "A high concentration of industry or population in a given area constitutes the best target for atomic or other modern weapons."[8]

In planning future communities, and in the redevelopment of existing cities, the dispersal of the populace is likely to be stressed as a security measure. The rate of migration outward from the urban center has been increasing for many years, and there will be no conflict of ideologies in the suburban movement. Serious questions may be raised, however, as to the wisdom of redeveloping urban slum areas and increasing population densities by the construction of vast apartment houses where small tenements stood previously. Psychiatrists and sociologists already have opposed the intensification of urbanization on the hypothesis that man lacks the compressibility of gas and tends to change his mental state at a comparatively low pressure. Defense planners seem to have a more easily recognized reason for curbing population concentrations.

A small committee of the American Institute of Architects is already studying the problems in architecture that

have arisen with the advent of the atomic age. They also are attempting to evaluate present architectural and planning principles as they may be influenced by the possibility of atomic or other unconventional methods of warfare. It is significant that the committee has called upon the Public Health Service for technical assistance in preparing its report.

Although numerous problems in the field of housing have resulted from recent scientific discoveries, many possible advantages may come out of this new knowledge. The harnessing of atomic energy and the development of electronics are likely to produce major changes in dwellings of the future. For example, cheap power and mechanization may alter completely the design of kitchens, and change the lot of the housewife so that she will have more leisure. This, in turn, should result in different functional requirements in the design of the rest of the house. Indeed, standards now recommended may rapidly become outmoded.

We need pedestrian research in the physical aspects of housing. But in the years to come there will be an even greater need for truly imaginative study of man in his social and physical environment. Out-of inspired studies may come the keys to a better understanding of the hygiene of housing.

In the meantime it is evident that there exists a wide gap between present knowledge and its application to the job of making dwellings sanitary. The engineer, the epidemiologist, and the health officer, all have the "know-how" now to improve the quality of the existing housing supply, and that which will be built in the near future. The job cannot be done by health departments alone. Rather, there must be coöperative planning and action by local health, building, planning, housing, and fire officials. Part of the framework for this impressive activity will be described by others in this symposium.

Diagnosis of Rabies

A one week course in the laboratory diagnosis of rabies, April 25 to 29, is announced by the Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga. The course will be held in Atlanta and is open to all grades of employed laboratory personnel. It will consist, essentially, of practical training in laboratory diagnostic procedures supplemented by lectures and demonstrations. There will be no tuition or laboratory fee. Apply to Ernest S. Tierkel, Asst. Chief, Veterinary Public Health Division.

Housing and Health

Appraisal of Substandard Housing *

EMIL A. TIBONI, M.P.H.

Special Consultant, U. S. Public Health Service; formerly Field Secretary, Committee on the Hygiene of Housing, American Public Health Association, New Haven, Conn.

THERE is a certain restlessness which is immediately apparent on the part of most public health engineers whenever the subject of housing arises. This reaction is usually traceable to three causes: (1) they are acutely aware of the existence of substandard housing in their communities; (2) they are keenly interested in increasing their activities in this field of sanitation; and (3) they do not have a clear idea of where or how to begin.

They recognize the fundamental truth of the statement of Winslow that "We shall make real progress in the elimination of our slums only when the health department has at its disposal a concise and quantitative picture of the actual current status of housing in each possible problem area of the city—such a picture as it now has with respect to the water supplies and dairies and food stores which serve the community." [1]

They are also aware that in many health departments which have made a sincere effort in this field, there exists a tragic monument to a lost cause. It is composed of row after row of cards, each of which bears the record of from one to several sanitary inspections of housing in the city.

It is a tragic monument, not only because of the expense involved in its creation, not only because the man hours which went into it could have been devoted instead to some more productive effort, but because most of the people affected are still living under deplorably unhealthful conditions, and there is no indication that it either has been or will be possible to use these records to do anything significant about the problem.

During the entire history of the public housing program, these records have not been used on any appreciable scale to produce information on local housing conditions.[2] This has been equally true in regard to the more recent urban redevelopment movement.

In a few communities, the health department has conducted systematic enforcement inspections of substandard housing in selected blocks as an adjunct to the community housing program. In these cities, public housing and urban redevelopment are still guided by the very limited information available from such sources as the 1940 Housing Census and the Real Property Surveys.

Even if we assume that the health department in such a program is well acquainted with the particular types of housing deficiencies prevalent in the community in order to have a sound basis for the development of standards and the promulgation of effective legislation—an assumption which is not always warranted—such an approach still suffers severely from lack of orientation to the overall housing conditions and fundamental planning requirements of the city.

---

* Presented before the Conference of Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

That the enforcement of legislation alone cannot effect a basic improvement of housing quality is well demonstrated by the editorial comment of a leading newspaper concerning the result of a long existent and exceptionally well administered systematic enforcement program. Commenting on an article in a national home builders' publication claiming extensive accomplishment for the program, the editorial stated in part "The slum clean-up campaign has brought about the replacement of window panes and plaster in some areas, improved sanitary conditions to some extent and compelled landlords and tenants alike to clear out rat-infested cellars and back yards. But the overcrowded, substandard buildings remain exactly that."

Systematic enforcement of this type can be tremendously useful if it is conducted in areas marked for rehabilitation and spot replanning. That, however, must come after the future use of all possible problem areas has been clearly determined.

In a number of cities, the health department has studied substandard housing on a broad scale before attempting more than emergency corrective action. It has pooled its resources and its problems with other city agencies including the planning, housing, and redevelopment agencies, as well as the enforcement agencies such as the building and fire departments.

In one small city, a study of *all* the suspected problem areas was conducted in a few months under the sponsorship of over 35 official and nonofficial agencies. In approximately a dozen other cities, permanent programs under the combined sponsorship of several departments have been in progress for periods ranging from a few weeks to several years. The results in five of these cities are described in a recent issue of *The American City* magazine.[3]

The key to these coöperative programs has been a method of evaluation which produces information on many aspects of housing in a single appraisal rather than considering sanitary, structural, sociological, or other defects separately and alone. This method, the A.P.H.A. housing appraisal method,[4] can produce a body of accurate objective information which is understandable and useful to all local agencies concerned with housing improvements. It can facilitate the formation of official policy by providing the facts needed to classify a city into four groups of areas:

1. Areas in which the dwellings and their environment meet an accepted local minimum standard of quality
2. Areas with moderately advanced blight but in which the dwellings and environment can be restored to an acceptable minimum standard by the enforcement of suitable legislation
3. Areas in which the dwellings are so poor that it would not be feasible to restore them to an acceptable minimum standard, thus making it advisable that they be demolished or converted to other suitable uses
4. Areas in which the environment is so poor that they should be cleared of housing and replanned for other uses regardless of the existing quality of dwellings

The replanning necessary for the improvement of certain areas will also require facts concerning the basic social and economic composition of the population. Much of this information too can be obtained from the descriptive data recorded concerning the dwellings and the occupants.

Where then does a community begin to establish studies of this type? Experience in such cities as Los Angeles, St. Louis, Philadelphia, Brookline, Mass., and Battle Creek, Mich., indicates that the primary requirement is the establishment of a coöperative working arrangement among the interested agencies. As the result of this coöperation, the man power or cash required for the appraisal of areas of mutual interest is brought well within the means of each of the participating agencies.

With the establishment of programs.

of systematic appraisal, many health departments have chosen to reduce the inspection of housing complaints to cases which may present serious hazards to health. They are instead assigning the nuisance complaint inspectors as a share of their contribution to the interagency appraisal program. Some building and fire departments are following a similar procedure. Despite great differences in the background of personnel contributed by the various agencies, workers produce virtually uniform results because of the objectivity of the appraisal procedures.

The results of these coöperative programs have been gratifying. Uses of data have ranged from the preparation of housing legislation and its enforcement through to the guidance of policy and the provision of working data for planning, rehousing, and urban redevelopment. In Los Angeles and St. Louis, the data have served to reveal significant local deficiencies which have been used as guides in preparing and securing the passage of new housing ordinances. In Battle Creek, the data are pointing the way toward the very first steps to be taken in a community which has not previously had a housing program of any type.

The use of the data for planning low-rent housing projects, the selection of tenants, and the systematic rehabilitation or condemnation of the vacated dwellings has been practised in many cities and has been particularly successful in Los Angeles. In all of the larger cities, an outstanding use of the data has been in the selection of areas and the preparation of plans for large-scale redevelopment. The appraisal in Philadelphia, which has been conducted primarily for this purpose, has covered areas totalling approximately 2,500 blocks and 125,000 dwelling units.

Training in the A.P.H.A. appraisal method, until recently available only on a consulting basis from the Committee on the Hygiene of Housing, can now be obtained without charge through the U. S. Public Health Service at the Training Division of the Communicable Disease Center in Atlanta. Information concerning this training may be found in the 1949 catalog of the Communicable Disease Center [5] which is available on request. The Public Health Service is also available for field service to agencies interested in establishing housing sanitation programs.

If we are to rid our communities of substandard housing, we must recognize that they are dynamic living organisms and treat them accordingly. We cannot much longer risk the searching experimental approach of the anatomist to the laboratory specimen. We must instead substitute the controlled approach of the surgeon, in order to be certain that we will remove all the decayed areas without at the same time destroying what is still useful. By intelligent planning and the selective enforcement of appropriate legislation, the factors causing decay can be controlled and much moderately substandard housing can be rehabilitated. By demolishing only the exact housing which cannot be salvaged, and enforcing the rehabilitation of that which can be saved, we may be able to reduce the job of eliminating our slums to practicable economic limits. In such a coöperative program, the health department has a vital part.

Housing and Health

The Provision of Good Housing *

CATHERINE BAUER
Department of Regional Planning, Harvard University, Cambridge, Mass.

THE sequence of talks at this session is a recapitulation of the ever widening field of concern in the evolution of the housing movement. The great "sanitary awakening" of the mid-19th century, which brought water and sewerage systems, was followed by increasing awareness of substandard qualities in dwelling structures per se, hence a wave of restrictive measures. Then came the positive effort to produce decent new dwellings to rehouse low-income families and provide an adequate supply of homes, which broadened in turn to the current emphasis on overall neighborhood and community planning.

It would be interesting to look at this history purely from the viewpoint of the health sciences, for it parallels and expresses the progress of scientific principles and purposes very neatly. Sanitary measures were undertaken to curb the fearful epidemics of filth-bred disease. Then gradually it became clear that not only the absence of dirt but the presence of sun, air, and adequate space are essential to the prevention of disease. And finally the whole emphasis changed from a remedial approach to more positive and constructive goals.

Dr. Winslow has probably done more than any other single individual to bring about this shift in emphasis, so I quote from him. In setting modern housing standards, he says, health "must be interpreted in the broadest sense, to include not only the avoidance of disease but also the positive attainment of mental and emotional well-being." And again, "Health means more than just staying alive. Health means vigor and efficiency and satisfaction in living." We are therefore concerned today not only with restrictive housing standards and the elimination of slums, but also with the provision of homes and neighborhoods that are *positively* good—a residential environment that promotes mental and social well-being as well as physical health per se.

Now if it could just be assumed that these evolving principles would gradually be put into practice—simply by the rational and more or less automatic application of the latest knowledge to concrete human problems under the benign rays of that old *deus ex machina*, "Progress"—the history of the housing movement would hardly be worth mentioning in a meeting like this one. Under such circumstances, if you scheduled a session on housing at all, it would be solely to hear about recent scientific developments likely to affect your own future work. And you would certainly not invite someone like me, with no status whatever as a scientist (hardly even as a lowly "social scientist"), to talk to you. Indeed, such people—I supposed we might best be classified as "agitators" in the housing and planning fields—would have to seek other employment entirely.

But here I am. It is all too obvious that the wheels of progress in housing matters have not been moving as

* Presented before the Conference of Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

smoothly or as rationally as they should have.

So perhaps it may be worth while to remind ourselves that the chronology of the housing movement can be viewed not only as a significant chapter in scientific history, but also as a very lively and important chapter in *political* history.

For every major step in housing progress in the past century has involved some public action, from the early English sanitary measures through the tortuous history of building codes to the U. S. Housing Act of 1937 and the successive proposals to deal with the current shortage. And public action in a democracy usually means political controversy, as was well evidenced by the wild and abortive career of the Taft-Ellender-Wagner Bill in the last session of Congress. Indeed, almost all discussion of the "housing problem" and its solution is now crystallized in political terms — even including the question of technological progress.

It might be claimed, however, that the political aspects of housing, no matter how noisy, are purely secondary and incidental. In an "advanced" country it might be held that, once science has demonstrated the need and the means, political action will be taken sooner or later to whatever extent is necessary to achieve the predetermined ends.

But such a theory gives cold comfort to homeless veterans or harassed local officials in the immediate housing crisis. I propose therefore to explore quite a different hypothesis, which may prove more illuminating as to the nature of our current difficulty. I suggest that political philosophy — the motivating forces behind public action and the application of scientific knowledge—is not secondary or incidental, but *paramount*.

Let us look back very briefly to an earlier illustration. Housing first became a lively political issue in England just about a hundred years ago, when the Earl of Shaftesbury put through the first piece of national housing legislation in 1851. Of course it was essentially an offshoot of the public health movement, whose first great triumph was the English Public Health Act of 1848.

What brought about these measures? Superficially the answer is simple: terrible epidemics on the one hand, and on the other a new faith in the remedial powers of science. But there is a curious time-sequence here which is worth remarking. For the sanitation movement was well under way *before* the need for it was scientifically proved through the development of bacteriology. Here I must turn once more to that indefatigable interpreter of medical history, Dr. Winslow, who wrote that "the scientific basis for the great sanitary awakening was merely a vague consciousness of a relation between filth and disease, colored by traditional Hippocratic doctrine of miasms." Pasteur made his great discoveries in the 1870's, but Chadwick published his classic survey of *The Sanitary Condition of the Labouring Population of Great Britain* a generation earlier, in 1842. And, equally significant, it sold 10,000 copies and started a wave of legislation all over the civilized world.

Clearly, refined scientific proof lagged behind both social conviction and political action. And, even more curiously, the political action was taken at the very zenith (and in the very stronghold) of the doctrine of *laissez-faire*, of every man for himself, and at a time when even the most horrendous results of untrammeled individualism were still excusable on the grim Malthusian argument that without misery there would shortly be overpopulation and general ruin . . . and also, it might be added, long before there was anything approximating universal suffrage to implement the demands of the underprivileged.

But there were other political forces just beginning to take shape: that mixed array of social motives and ideals

which went into what is usually called the "humanitarian" movement. The early health and housing measures were among the first important political expressions of this movement, but its springs go back, undoubtedly, to the 18th century concern for the rights of the individual and the whole hopeful concept of the responsible, perfectible human being which stimulated the rise of democracy.

This was the broad sweep. But the public concern for physical welfare, as distinguished from civil liberties, suffrage, and popular education, can probably be more directly traced to the movement that gradually reformed the English Poor Laws beginning in the early 19th century. These reforms were slow and feeble, but they nevertheless established a world-shaking principle. Henceforth modern society could not just let people die, whether from starvation or sickness, no matter what the dismal science preached. Some minimum care and subsistence had to be provided.

The moment this principle was accepted, the health and housing movements were inevitable, not only on idealistic grounds (or because epidemics spread from slums to other areas), but for economic reasons as well. The taxpayers had an interest, whether recognized or not, in keeping people healthy, just as they had an interest, however disregarded until much later, in keeping people employed at a decent wage. James Tobey, another eminent historian of the health movement, put it baldly: "The first public health reform in England can be said to be really the direct consequence of the Poor Laws, for it was the desire to reduce the enormous expense of caring for sickness which led to this public health act."

Thus was born—out of democratic ideals, fear, and prudence—the principle of "minimum standards," available to all and implemented by public action where necessary, a principle which of course fathered the whole social security movement as well as health and housing measures.

Perhaps this partial economic interpretation sounds cynical? But the intellectual climate of the Victorian era was not one of extravagant idealism, and all reform was likely to be frankly tempered by more practical considerations one way or the other, to put it mildly. Sir Edwin Chadwick, the selfless agitator who had initiated the entire health movement almost singlehanded, was using the language of the times when he devoted a lengthy address to hard-boiled pounds-and-pence arguments for social reform:

"I venture to invite your consideration of men as an investment in capital," he said to the National Association for the Promotion of Social Science in 1869, "as a pecuniary, 'a transaction,' in relation to which we have to consider the means of rearing him with the view to the return of the highest percentage of profit over and above the cost of his nurture . . . upon that investment." When he turns his attention to Glasgow and Manchester, where half the babies then died before their fifth year and the rest were early debilitated, he argues that "this waste of national stock is as it would be with the farmer, if he had to rear two colts to obtain one working horse, and as if the horse when reared did not last in working or productive condition, much of half its natural time."

It was not until the 1930's that we in America began to get a flood of earnest local studies demonstrating that "Slums Cost Money," but the argument had a venerable tradition behind it. Edith Elmer Wood was appealing to the spirit of "enlightened self-interest" in housing matters when she lifted quotes from *U.S.D.A. Farmers' Bulletins* with such effective irony. Some of you doubtless remember them. One was: "Proper housing is an important factor in the successful raising of hogs. If

little pigs are to get the right start in life, they must have plenty of sunshine." And another: "Growing chicks and laying hens need comfortable houses that are dry and roomy, with plenty of fresh air and sunlight. It never pays to overcrowd them."

It seems clear that one of the historic mainsprings of housing reform is the political principle that maintenance of certain essential minimum standards is in the *public interest*.

This principle is, as a matter of fact, quite generally accepted in the United States today, even with respect to housing. Such an eminent conservative as Senator Robert Taft made no headlines when he said in a Congressional hearing, "The Federal Government is committed to a policy of housing . . . on a social welfare ground. We are interested in providing a floor under essential services so we can eliminate, as far as possible, extreme poverty and hardships from the United States . . . Housing is one of those things."

Why, then, are we not farther along toward a solution of the housing problem? Why, when it is so clear that ordinary private enterprise cannot possibly solve the shortage or get rid of the slums by itself, has it been so difficult to revive even a token program of federal aid for low rent public housing? Why is the housing situation in 1948 in the richest country in the world worse than it is in the Scandinavian countries, worse even in some respects than in England, despite all their wartime destruction and post-war economic crises?

Certainly there is no lack of proof that bad housing conditions are socially harmful, no lack of knowledge as to what an acceptable "minimum standard" in housing should include.

Perhaps the principle of "minimum standards" is not enough to galvanize us into positive action, after all. The fact is that the progressive European democracies have within the past generation accepted an additional and much more dynamic political principle with respect to housing. With the rise of social democratic parties and labor and coöperative organizations, the *direct* interest of ordinary consumers and wage earners (as distinct from the "enlightened self-interest" of the early humanitarians) began to make itself felt in housing matters. And with it came a new political concept: *the right to a decent home*. Henceforth it was not just a question of "minimum standards" to allay disease or prevent divorce or save the taxpayers money (or of sporadic housing programs tied to one emergency kite or another, to provide employment or increase the birth rate or improve the physical qualities of soldiers or lessen the danger of revolution), but good housing for all, to be provided by public action where private enterprise could not do the job, on the fundamental democratic principle of *equal opportunity*. It was on this basis that the remarkable inter-war housing achievement in several European countries was brought about.

Nor is this principle unrecognized in America. Indeed, it has never been better stated anywhere than by the Committee on the Hygiene of Housing of the American Public Health Association, whom I am happy to quote in such appropriate surroundings: "The case for proper housing for our people does not depend upon . . . evidence that the provision of good homes in good neighborhoods lowers death rates or reduces sickness. It has ample justification in the democratic principle that people are entitled to an opportunity for good homes just as they are entitled to an opportunity for education."

But we have not yet accepted this principle in America in any effective political sense. We have had a series of emergencies; in fact there has been one kind of housing crisis or another almost continuously ever since 1917, and the

present shortage has been developing ever since 1930. We have also had a hectic succession of emergency measures, some sound though limited, some partly or wholly opportunist. But we have nothing remotely resembling a broad, well considered long-term national housing policy. And most of our failure and confusion to date are due, I think, to the simple fact that we have not yet accepted the principle that American families are *entitled* to decent homes.

Syrup of Urethane and Lithium Salt Substitutes Embargoed

The Food and Drug Administration, Federal Security Agency, Washington, D. C., has recently had occasion to issue several warnings dealing with drugs which are of considerable public health interest.

The Administration has directed seizures of Syrup of Urethane, a cough syrup manufactured by Marvin R. Thompson, Inc., Stamford, Conn. Physicians, pharmacists and consumers are warned that the administration of urethane in the quantity recommended on the label may cause a dangerous lowering of the white blood cell count. More than 2,300 gallons of the syrup have been distributed in about 3,400 packages throughout the country. The coöperation of public health workers in locating and embargoing this product is requested in view of the obvious difficulty in locating all samples promptly.

According to the Administration, the drug urethane has been used as a sedative for about 100 years, but recent medical studies indicate its potential danger when used as directed in the labeling of this syrup. Most cases, however, discontinuing the use of urethane, result in the return of the white blood cell count to normal in a short time.

The Food and Drug Administration has also declared that there is considerable doubt as to the safety of unrestricted use of any salt substitute in the presence of cardiovascular-renal disease and a low sodium diet. The Administration has declared that each salt substitute is a new drug within the meaning of the Federal Food, Drug, and Cosmetic Act, and that interstate distribution of each salt substitute should be discontinued until a new drug application has been filed and has become effective with respect to the substitute.

Recent experiments on lithium chloride made by the Administration show that it is toxic to animals, and untoward reactions in man appear to have resulted from the consumption of lithium chloride.

On February 18 the Administration learned of deaths attributed to lithium chloride and through public announcements of the dangers it has advised that the use of this drug be discontinued. The symptoms of lithium chloride poisoning are drowsiness, weakness, loss of appetite, nausea, tremors of the extremities, blurring of the vision, and coma.

Housing and Health

The Planned Community *

FREDERICK J. ADAMS

Head, Department of City and Regional Planning Massachusetts Institute of Technology, Cambridge, Mass.

IF there is one point on which planning and housing experts have reached agreement it is that the home is more than a dwelling unit, or even more than a collection of dwelling units. All members of the family today spend a considerable portion of the daylight and evening hours outside the house, and housing environment has come to be recognized as equal in importance to the dwelling unit itself. In planning our communities and our large-scale housing developments, therefore, we must consider the relationship of the dwelling not only to the private space which surrounds it but also to the public facilities for recreation, education and culture, and to neighborhood shopping and transportation centers.

Clarence Perry has defined housing environment as comprising "that area which embraces all the public facilities and conditions required by the average family for its comfort and proper development within the vicinity of the dwelling."[1] Whether or not we agree that the word "*neighborhood*" accurately describes such an area in its physical concept, it is generally agreed that it represents the minimum area for the purposes of comprehensive planning.

The A.P.H.A. Committee on the Hygiene of Housing, on which I have had the pleasure of serving during the past 10 years, has adopted Perry's concept of the neighborhood and in its recently published report entitled, *Planning the Neighborhood*, states that:

> Acceptance of the neighborhood concept implies that adequate housing consists not merely of the individual homes, no matter how well planned or how well located; but that all residential and community facilities and services required for the shelter, health and convenience of the residents of a neighborhood must be included in a neighborhood—or must be made available to its residents.[2]

The committee further states that,

> Standards for housing environment must deal at least with the smallest geographic unit which includes those basic facilities and conditions; a unit which will permit organization of physical surroundings to eliminate inconveniences and hazards; and which will provide a physical form suitable for the full development of community life.[3]

In addition to community facilities for education, recreation, shopping, and transportation, provision must also be made for water supply, light and fuel supply, telephone, storm water and sewage disposal, other waste disposal, fire protection, and police service.

If we recognize the importance of the housing environment to the health, safety, and general welfare of our urban and rural population, it is essential that we come to some agreement on the ways and means of attaining our objectives. I do not have time, within the limits of this short paper, to describe and justify the standards of neighborhood or community design which must be adopted if we are to raise the quality of family living in our residential areas. In any case, a full description will be found in the report of the Committee

* Presented before the Conference of Municipal Public Health Engineers and the Engineering Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

on the Hygiene of Housing to which I have already referred.

As practitioners in the field of public health, I believe you would be particularly interested in the administrative and legal means that are available to, or desirable for, the average American community in the proper development of its residential areas. You come in direct contact with many of these in your everyday work and in the case of some, such as housing and sanitary codes and building regulations, you have had a considerable influence on their adoption and enforcement.

The chief legal means for the proper control and guidance of land development in this country are Master Plans and Official Maps; Zoning Ordinances; and Subdivision Regulations. These are closely related controls, but I will discuss them in turn.

The concept of the Master or Comprehensive Plan, as it has developed in the United States, is not a single map but a program. It is comprehensive in scope, and involves all matters affecting the development and redevelopment of a city or region. It represents the best thinking of the planning agency, aided by all other departments of the government that are affected. The Master Plan deals with such problems as land utilization, highways and transportation, schools and recreation, water supply and sewage disposal, and housing. Such a plan should be considered as a guide to future development rather than as a blueprint for a specific construction program, for which reason the proper timing of projects should be given as much consideration as their location or design.

The methods by which the Master Plan is used to control future development vary in different parts of the United States, depending on state enabling legislation and local ordinances. However, the usual procedure is to require that no physical improvements in a municipality may be carried out by an operating department unless they conform to the Master Plan. A less stringent control occurs where only a report from the planning agency is required before action can be taken by an operating department. In recent legislation in the United States providing for the redevelopment of blighted areas in cities, it is required that plans for redevelopment be in accordance with the Master Plan for the whole city, and that the planning agency designate the general type of development appropriate to each area.

In the legislative aspects of planning, much progress which has been made in recent years is in the field of Zoning. In the United States, the legal basis for this phase of planning activity is the police power. This means that each ordinance must be confined to dealing with problems relating to the "health, safety, morals, convenience, and general welfare" of the community. For this reason, zoning regulations in different parts of the country are quite similar, although some states go further than others in the delegation of powers to local authorities. The development of zoning came about primarily because of the need for improved conditions of light and air in and around buildings. It also stemmed from a desire to preserve the character of established residential districts by protecting them from an intermixture of commercial and industrial uses. More recently, restrictions on population density have been incorporated in many zoning ordinances, usually by specifying the minimum size of lot upon which a dwelling may be built. In the case of multi-family districts, the minimum area of lot per family is specified. Some residential districts in outlying suburban communities have enacted ordinances containing minimum lot sizes of from one to five acres.

Zoning also provides an effective means of preventing the development of land unsuitable for any intensive pur-

pose. What is commonly known as "Rural Zoning" has as its object the restricting of large undeveloped areas to forestry or recreational uses. In a number of states, rural zoning has been successfully used to prevent the construction of residential or commercial buildings on sub-marginal land or within the boundaries of flood plains.

Next in importance to zoning, in the procedures which make possible the better planning of urban and rural areas, is the use of regulations dealing with Subdivision Control. In the past these have generally been confined to restrictions governing the location, width and grading of streets, in order to insure that future connections can be made with water and sewer mains and that streets can be properly drained of surface water. Such regulations are usually administered by the engineering or public works department of the community, or in some cases by a separate agency such as the Board of Survey in Massachusetts. There is a strong tendency toward placing this power in the hands of the local planning commission, which in the past has acted in an advisory capacity only. This has made possible a much closer relationship between control over the private subdivision of land and the planning of public streets, buildings, and open spaces.

We are inclined to minimize the efforts of those architects and engineers of the 19th century who worked for the enactment of adequate planning legislation. In a study I made 12 years ago for the Massachusetts State Planning Board on the history of community planning in Massachusetts, I came across the following quotation from a report prepared by N. Henry Crafts, a Boston consulting engineer, who was engaged to prepare a plan for the future extension of the sewer system of the City of Haverhill. In connection with this plan Mr. Crafts found it necessary to lay out a number of new streets, and his report to the city includes the following proposal:

> I would make it unlawful for the owner of any undeveloped lands within the limits of such towns or cities as may accept the proposed legislation, to lay out any proposed streets, ways, or courts, or to proceed to build the same, or to sell land bordering upon such prospective streets, ways, or courts without first giving notice to the proper authorities, filing a plan showing the proposed location and grades of the street and receiving a permit. In this way, the whole matter of the location of streets on undeveloped lands may be controlled and directed in such a manner as to obviate the extravagant outlays which almost every town or city of my acquaintance has had to incur in street widenings, extensions, and changes of grade.[4]

This report was published in 1877—just 71 years ago—but it was 30 years later before the Board of Survey Act was passed by the General Court in Massachusetts and nearly 60 years went by before planning boards were granted general powers of control over subdivision design.

It is unfortunate that the aspects of zoning and subdivision control in the United States have been separated from planning to a greater extent than is the case in other countries. One of the results of this has been the enactment of zoning regulations in communities which have prepared no plans for future physical development. Zoning then becomes an instrument for maintaining the status quo. At best it results in the protection of existing developed areas from invasion by uncongenial uses of buildings or land. However, the tendency on the part of most planning agencies is definitely in the direction of a closer coordination of planning and zoning. In the preparation of new zoning ordinances and the revision of existing ones, more effort is being made to relate areas set aside for different uses to the probabilities of development. This attitude has been stimulated by the fact that the rates of growth for both population

and land values in the central areas of many large cities are downward. For the same reason, zoning regulations are tending to become more restrictive, particularly as they affect building height and coverage and population density.

One example might be mentioned to indicate how planning is becoming recognized as an essential factor in the improvement of community values. The broad powers granted to the City Planning Commission under the charter adopted by New York City in 1938 may be considered a case in point. Here a department of government, which formerly had been acting only in an advisory capacity, was vested with the responsibility for regulating and coördinating all elements in the physical development of the community. It is worth noting that the City Planning Commission of New York is responsible not only for the preparation of a Master Plan dealing with future developments such as streets, parks, buildings, utilities, and other services. It is also responsible for the preparation of the capital outlay budget, a long-term financial program based on individual requests for appropriations submitted to the Commission by the heads of city departments. During the past 10 years, this procedure has been officially adopted by a number of other cities and towns.

I think I have said enough to indicate that most of our communities have sufficient power to carry on an effective planning program if they choose to do so. Why is it, then, that so much of our residential and commercial development is continuing to follow patterns which are socially and economically undesirable? Some of the responsibility can doubtless be placed on professional planners and on members of planning commissions. Many of the latter are not fully alive to the opportunities for sound community planning that are available to them under existing legislation. They suffer from inadequate budgets, disagreement as to social objectives, and a certain amount of interdepartmental jealousy. There is an insufficient supply of qualified planning technicians and consultants, and to some of these expediency is a more controlling factor than imagination.

However, I do not believe it is on the shoulders of our planning commissions or of our professional planners that we can place the major responsibility for our failure to achieve the goal of the Planned Community. If the majority of our citizens were convinced of the desirability of exercising foresight in the future development of our cities and towns, no city council or board of selectmen could be elected which ignored the principles of sound planning.

Planning is just as much a political and administrative function as a technical one. Until long-range planning and pragramming is recognized as an integral part of government in a democratic society, at the policy making as well as the departmental level, it is idle for us to draw up beautiful master plans and elaborate reports showing the way in which we would like to see community development take place. The day of the Planned Community will come only when foresight and teamwork is recognized as the joint responsibility of architects, engineers, planners, municipal officials, and the great body of the public for whom the plans are being made.

The public is quick to recognize that on it falls the cost of planning and development. Perhaps when it is equally well understood that it is the public which must pay the price for *not* planning, we will be well on the road to the Planned Community.

Q Fever

History and Present Status *

R. E. DYER, M.D., F.A.P.H.A.

National Institutes of Health, U. S. Public Health Service, Bethesda, Md.

MUCH progress has been made in our knowledge of Q fever since it was first described in 1937. The story had two beginnings at about the same time curiously enough; one in Australia, the other in the United States. In each instance an infectious agent was isolated and classified as a rickettsia. These infectious agents, isolated on opposite sides of the globe, were soon shown to be identical.

In 1940 this disease, scarcely considered as of more than minor importance up to that time, suddenly assumed greater stature when, through the study of a laboratory outbreak, it was found to produce a pneumonitis and clinically in many instances to resemble the atypical pneumonias. At the present time the known endemic areas, spotted with epidemics, are widely scattered over the globe—Australia, the United States, various countries of the Mediterranean area, Panama, and Switzerland. Finally, Q fever has added one more to the ever increasing list of animal diseases transmissible to man.

In 1937 Derrick [1] published a report on cases of a hitherto unrecognized disease entity which had been occurring in a large abattoir in Brisbane, Australia, since 1933. To this disease he gave the name Q fever. In his original report he described nine cases in detail while brief notes on additional cases resulting from laboratory infections were made by Burnet and Freeman,[2] and by Smith, Brown, and Derrick.[3]

It has been stated in the literature that the name Q fever was given the disease because it was first described in the state of Queensland, Australia. This apparently is in error. Derrick and Burnet [4] give interesting accounts of the choice of the name.

In the early investigations the disease was known as abattoir fever. This seemed undesirable on account of implications of possible danger to meat supplies, and also on account of probable objections on the part of the industry. It soon became clear to the Australian investigators that the disease was also present on farms. Derrick tried to find a suitable name of Latin or Greek derivation without success and finally chose "Q" fever, the "Q" standing for "Query." The name, "Queensland Rickettsiosis" was discussed, but rejected, as it was thought cases might be found outside of Queensland. It is evident from the foregoing that the use of the name Queensland fever is historically incorrect.

Although many additional cases have been reported by Australian investigators, no very definite epidemiological deductions have been drawn. As has been noted, the cases first reported by them occurred among workers in an abattoir. The individuals affected were not engaged in the same activities in their daily work, nor did they work in any particular section of the abattoir, and there was no evidence which would suggest person-to-person transmission.

* Presented before the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 12, 1948.

Using serologic methods, cases have been identified in Australia outside the original Australian focus. These cases have been among foresters and dairy workers.

In the abattoir we at once think of the possibility of acquiring infection through actual contact with the animals in process of slaughtering and preparation of animal products, or by infected air-borne particles containing matter from animal sources. In cases among farmers that source of infection is probably present, as it may be among foresters, but the rural group also suggests contact with infected arthropods.

Derrick [5] succeeded in transferring the infectious agent of Q fever from some of his cases to guinea pigs by blood inoculation, and later he and his colleagues found other common laboratory animals and several species of native rodents and three native marsupials to be susceptible. Burnet [6] found that the etiological agent passed through bacterial filters and discovered rickettsia-like bodies in the spleens of infected mice. He was able to grow these organisms on the chorio-allantoic membrane of the developing chick embryo. Derrick [7] subsequently suggested the name, *Rickettsia burneti,* for the organism observed by Burnet.

Probably influenced by the fact that the etiologic agent appeared to be rickettsial in nature rather than by any definite epidemiological evidence, Derrick and Smith [8, 9] made search for infected animals and infected arthropods in nature and succeeded in isolating three strains of *R. burneti* from bandicoots and six strains of the organism from ticks (*H. humerosa*). Smith [10] was able to show transmission of the infection to guinea pigs by infected ticks of the same species during the process of feeding.

In 1938, Davis and Cox,[11] and Parker and Davis [12] at the Rocky Mountain Laboratory at Hamilton, Mont., reported the isolation of a filter-passing agent, infectious for laboratory animals, from the tick *Dermacentor andersoni.* The ticks from which this infectious agent were recovered had been collected in the spring of 1935 near Missoula, Mont., at a place called Nine Mile Creek, and the disease produced in animals was called "Nine Mile Fever." This name was used in one of the early publications. The authors noted in their first publication that this was probably the same infectious agent encountered by Noguchi in 1926 under similar circumstances.

The Montana workers described a rickettsia-like organism which was associated with the new infection and named it *Rickettsia diaporica* on account of its ability to pass through ordinary bacterial filters, differing, in this characteristic, from other recognized rickettsiae. In the laboratory it was noted that this rickettsia was transmitted to susceptible animals by *D. andersoni* in the process of feeding, and that it survived in ticks through successive moults and through the egg stage.

Cox [13–15] failed in attempts to cultivate this organism on a wide variety of media, including all those found suitable for the growth of such organisms as tularense, leptospira, and bartonella, but found that it grew readily in living tissue cultures.

Since the early work in Australia and Montana, several species of ticks have been found infected in nature or have been shown to be able to transmit the infection experimentally, but aside from occasional incident, it does not seem that ticks play an important part in the transmission of the disease to man, although they may be important factors in maintaining the disease in nature. The ticks so far incriminated are *Dermacentor andersoni,*[11] *Dermacentor occidentalis,*[16] *Rhipicephalus sanguineus,*[17] *Ixodes holocyclus,*[18] *Haemaphy-*

salis bispinosa,[19] *Ornithodoros moubata*, *Ornithodoros hermsi*,[20] *Amblyomma americanum*,[21] *Hyalomma savignyi*,[22] and the spinous ear tick, *Otobius megnini*.[23]

In 1938 one of the workers[24] of the staff of the National Institute of Health, Washington, D. C., spent 4 days in the laboratory in Montana where the infectious agent isolated by Davis and Cox from Montana ticks was being carried in laboratory animals. This worker returned to Washington and there developed an illness of about 10 days' duration; the incubation period was from 11 to 15 days. From his blood an infectious agent was isolated in guinea pigs and identified as the same infectious agent as was under study in Montana, (*R. diaporica*). How the disease was contracted in the Montana laboratory was never determined. This strain, called the X or Dyer strain, was studied in animals and found to produce no immunity against strains of Rocky Mountain spotted fever and typhus. As it happened, the individual who had contracted the Montana infection, had been working in the laboratory in Washington with the Australian Q strain which had been sent to him by Burnet. This strain had been lost several weeks before the time of his illness, but five recovered guinea pigs remained on hand. These animals were found to be immune to the Montana strain. A second strain of the Q fever organism was secured from the Australian workers and serological and immunological comparison with the Dyer strain showed that these strains were at least closely related, if not identical.[25, 26] Subsequently, work by Burnet and Freeman[27] in Australia confirmed these findings.

The knowledge of this disease and of the causative agent up to the spring of 1940 may be summarized as follows:

An infectious agent had been isolated from human cases of illness, and from naturally infected bandicoots and ticks in Australia, and identified as a rickettsia. A rickettsia had been isolated from ticks in Montana and, by accidental laboratory infection, had been found to be infectious for human beings. These two rickettsiae had been shown to have at least a very close relationship, being serologically and immunologically identical. These rickettsiae, or this rickettsia, had been shown to be present in arthropods in nature, and naturally infected animals had been found in Australia, and the conclusion seemed warranted that this disease was arthropod-borne in nature.

Although the etiologic agent of Q fever was classified as a rickettsia, it was recognized early that certain differences exist between it and all the other rickettsiae. Morphologically and in its tinctorial and cultural characteristics it belongs with the other rickettsiae. On the other hand, it does not develop agglutinins for any known strain of Proteus, and it readily passes bacterial filters. These variations, coupled with the fact that the organism shows greater resistance to physical and chemical agents than other rickettsiae,[33] justify the setting up of the Q fever organism as the type organism of a new genus, Coxiella (Philip 1943), hence, *Coxiella burnetii* supersedes *R. burneti* and *R. diaporica*.[28]

A few cases, apparently contracted in nature, have been reported in this country,[29, 30] but convincing epidemiological evidence incriminating arthropods as transmitters to human beings is lacking. Until the spring of 1940 we had the picture of a rickettsial disease fairly widespread and probably arthropod-transmitted from one or more animal reservoirs with probably some human cases being contracted directly from infected animals. At that time, there was no suggestion of pneumonic involvement in human cases.

The originally held ideas of this disease changed rather abruptly in the

period from March 27 to May 17, 1940. During that time 15 clinically similar cases of infection occurred in one of the buildings of the National Institute of Health in Washington, D. C. From 3 of these cases, strains of the infectious agent of Q fever were isolated by Dyer, Topping, and Bengtson.[31] At that time two strains of Q fever were being carried in animals in the building. One of these strains was the original strain from Australia, while the second was the Dyer strain isolated from the first Washington case of 1938.

A careful investigation of the 15 cases at the National Institute of Health revealed little of epidemiological significance. The cases occurred in persons who worked in various sections of the building, with the exception that no cases developed in those employed in the group of rooms in which actual work on Q fever was being carried on. The most reasonable explanation of the absence of cases among those actually exposed in these rooms to animals infected with Q fever lies in the possibility of immunity produced by unrecognized infections. That this might be the correct explanation was suggested by the presence of Q fever rickettsia agglutinins in low titers found in the sera of 6 of the 10 persons working in the Q fever unit as compared to 4 of 20 persons working elsewhere in the building exclusive of those having a recognized infection with Q fever.

There was no evidence that the disease spread in the building by personal contact, nor were there any recognized cases in the families of the patients, nor was there any evidence that an arthropod vector was responsible for the transmission of the infectious agent. However, since the cases were limited to the building in which the disease was being studied, it seemed probable that the disease spread from infected laboratory animals or embryo cultures in some fashion, possibly being carried throughout the building by dust. Later in the year (September to November) 2 additional cases occurred in the same building. From each of these cases the infectious agent was isolated. Transfer of the Washington Q fever laboratory was made to new quarters in 1941. In the winter and spring of 1945 and 1946 (December to May), 47 cases of the disease occurred among the persons working in the building. The epidemiological findings corresponded closely to the indefinite findings of the previous outbreak.[32, 33]

At the time of the first outbreak at the National Institute of Health, the possibility of the presence of similar unrecognized cases in the general population was considered. This seemed possible since the causative agent was probably widespread in nature and since the clinical features of the disease bore a remarkable similarity[34] to the so-called cases of atypical pneumonia which had been reported in the medical literature with increasing frequency since Bowen's[35] report of 1935. Consequently, shortly after the initial outbreak at the National Institute of Health, thorough study was made of two institutional outbreaks of atypical pneumonia in an effort to determine their relationship to Q fever. The results were entirely negative.[36–38]

The cases described in Australia, and the later cases in Washington did not differ materially in the clinical pictures, and this is true of cases subsequently reported from other parts of the world. Additional clinical findings of lung involvement not noted in the Australia cases were brought out in the Washington cases. It is not the purpose of this paper to discuss the clinical picture, but it is important to stress the clinical similarity of Q fever cases with cases of atypical pneumonia. The case fatality rate is very low. Four deaths have been reported in this country to date, and two in Australia. A case fatality rate

less than one per cent is reported for Balkan grippe.

An outbreak resembling influenza occurred in Athens, Greece, in 1943. From a patient in this outbreak, Caminopetros [39] recovered an organism which was later shown to be *C. burnetii*. This disease was shown to be endemic in that area during the war and was called "Balkan Grippe" by the Germans.[40–42]

The presence of the organism in cows' milk has been reported in this country,[43] and in Greece, sheep and goats and their milk have been shown to harbor Q fever.[39] The disease probably exists in other countries in that region—Bulgaria and Roumania.[44, 45]

In 1944 and 1945, Robbins, et al., recognized epidemics of Q fever in the U. S. troops in Italy.[46–48] The findings in the study of these outbreaks confirmed the observations made during the laboratory outbreak at the National Institute of Health in 1940, that person-to-person contact was not important in the transmission of this infection, if, in reality, it ever occurred. This, in spite of the fact that *C. burnetii* has been recovered from the blood, urine, and sputum of patients suffering from the disease.

At about the same time (1945),[49] a strain of the organism of Q gever was recovered from a patient in Panama, the disease apparently being endemic in that area.

Outbreaks of Q fever also occurred among our troops returning from Italy.[50, 51] Comparison of various strains of *C. burnetii* (Australia, America, Balkan grippe, Fort Bragg, Panama, Italy) by Topping, Shepard, and Huebner [52] showed complete cross-immunity in guinea pigs while complement-fixation and agglutinin absorption tests showed similarity in immunological specificity.

In the outbreaks among our troops in Italy, association with domestic livestock, hay, and bedding was noted. Pigeons were numerous around the billets in some instances, but in one instance were absent. Arthropod transmission did not appear likely. It is interesting to note that complement-fixing antibodies were found in the blood sera of a large proportion of the native population in the Italian areas around army troops.

Laboratory cases were also reported at Fort Bragg, North Carolina.[53] In 1947, Caughey and Dudgeon,[54] reviewing 511 cases which had occurred among British and New Zealand troops in the Naples-Caserta area in 1945, with the aid of the complement-fixation test carried out at the National Institute of Health, found that 19 of 20 sera tested were positive for Q fever.

In 1948, Gsell [55] reported cases of illness which had occurred in Switzerland in April, 1947. The identity of these cases with Q fever was confirmed by Cox, using the complement-fixation test. Association with cattle was noted in these cases.

In the United States, although it was realized that the disease was probably present, no evidence of endemicity was obtained until 1946 when outbreaks occurred among abattoir and stockyard workers (reminiscent of the first Australian cases) in Amarillo, Tex.,[56–59] and Chicago, Ill.[60] Again, in these outbreaks, just as in the institutional outbreaks at the National Institute of Health and the Italian epidemics, the most likely mode of infection seemed to be the inhalation of, or contact with, infected material, most probably from infected animals. In this country the disease has also been recognized in Arizona [61] and Montana.[30]

In 1947, cases were recognized in Los Angeles County, California.[62] The first cases were not among abattoir or dairy workers,[63] but practically all gave history of exposure to cows, some of which were found to possess serum antibodies for Q fever. Further studies in Califor-

nia, which are being continued by the California State Department of Public Health, Los Angeles County and Los Angeles City Health Departments, and the U. S. Public Health Service, have shown that *C. burnetii* is present in raw milk[43] produced in the area, but the importance of infected milk as a factor in the transmission of the disease to man is not yet determined. Early experiments indicated that pasteurization eliminated most if not all of the demonstrable infection in milk. Contact with livestock by reason of occupation or residence, at present, seems to be an important factor. This was also suggested by the findings in the Balkan area.

Work has been done in the preparation of vaccines by Cox,[15] Bengtson,[64] and by Smadel.[65] Laboratory experiments indicate their value, but no field data are available as to protecting man against the infection. It should be noted that no cases of Q fever have occurred among laboratory workers who have been vaccinated. Huebner, Hottle, and Robinson[66] have produced some evidence that streptomycin may be of value in treatment.

SUMMARY

In Q fever we have a disease with known potential sources of infection in infected cows, sheep, goats, the milk of these animals, wild animals, and a wide variety of ticks. Epidemiologic studies of the occurrence of Q fever in abattoir workers, laboratory workers, dairy workers, and residents of dairy areas indicate that an important method of transfer of the infection to man is through the medium of contaminated air, whether this be by droplet infection or by dust.

Q Fever

Experimental Q Fever in Cattle * †

E. J. BELL, Sc.D., R. R. PARKER, PH.D., AND H. G. STOENNER, D.V.M.

Scientist (R), and Director, Rocky Mountain Laboratory, U. S. Public Health Service; and Assistant Veterinarian, Communicable Disease Center, U. S. Public Health Service, Hamilton, Mont.

THE purpose of this paper is to present briefly some of the results obtained following the inoculation, or other controlled exposure, of cattle to *Coxiella burnetii*, the causal agent of Q fever.

Much of the evidence derived from epidemiologic studies of Q fever has emphasized the importance of contact with livestock as a means of human infection. The Australian investigators were the first to note that the disease occurred primarily among dairy farmers and abattoir workers.[1, 2] In the United States, the naturally occurring outbreaks in Amarillo, Tex.,[3] and in Chicago, Ill.,[4] were also associated with stockyards and slaughter-houses. Furthermore, it seemed clear from studies of these latter outbreaks that infected cattle in Amarillo and infected calves or sheep in Chicago had been the source of human infection.

The occurrence of natural Q fever infection in cattle was first indicated serologically,[1, 5] and was later confirmed [6] by the recovery of *C. burnetii* from raw milk of several dairies in Los Angeles County, California. As might be expected from these findings and from the epidemiologic observations noted above, this disease was found to be endemic in Southern California.[7] Studies of over 150 human cases in this area revealed that 40 per cent had had some contact with livestock.

Although the importance of cattle as a source of human infection seems established, the epizoölogy of this disease is not obvious, nor is it clear by what means infection may be transmitted from cattle to man. With these questions in mind, controlled laboratory studies of the experimental infection of cattle with Q fever were initiated. It was believed that information derived from such studies might be of considerable value, especially in planning investigations of this disease as it occurs in nature.

Experimental infection of cattle with Q fever has been reported previously by Derrick, Smith, and Brown [1] in 1942 in Australia and by Blanc, *et al.*[8] in 1948 in Morocco. The Australian investigators reported the results of the subcutaneous inoculation of two calves with infected guinea pig tissue. Both calves manifested a mild febrile reaction for one day, the 3rd day after inoculation. One was sacrificed on the 4th day and *C. burnetii* was recovered from the spleen and liver. The infective agent was also recovered from a 4th day blood specimen of the second calf, and Q fever antibodies were detected in its serum from the 11th to the 29th day. Blanc

and his associates, working in Morocco, state that they were able to infect cattle with this disease, and that these animals showed a mild febrile reaction followed by the development of agglutinating antibodies for *C. burnetii*.

METHODS AND MATERIALS

A more detailed description of the experiments to be reviewed in this paper is included in other manuscripts now in press or in preparation for publication. The various materials obtained from experimental cattle were tested for infectivity by injecting them into guinea pigs. Guinea pigs were bled approximately 30 days after inoculation and their sera tested for Q fever antibodies by the complement-fixation test. Subsequent to bleeding, the animals were tested for immunity by inoculation with a known strain of Q fever. The development of antibodies in the sera of guinea pigs and immunity to reinfection with *C. burnetii* were regarded as evidence that the material injected was infected. Prior to inoculation, the cows were shown not to have specific serum antibodies and their milk and blood were shown not to be infectious for guinea pigs.

EXPERIMENTAL

Studies of experimental Q fever in cattle were begun at the Rocky Mountain Laboratory in 1947.[9, 10] The initial work involved attempted infection of 4 heifers which were inoculated by different routes, namely, intranasal, intravenous, by way of the alimentary tract, and by way of the vaginal tract. Specimens of blood, nasal washings, feces, and urine, taken at 5 day intervals for a period of one month, were tested for infectiousness in guinea pigs. Results of these four experiments were apparently negative.

Subsequent to these initial studies, additional experiments involving 9 lactating cows, 2 male calves, and 1 heifer, have been undertaken. Seven of the cows were inoculated with Q-fever-infected yolk-sac cultures, and 2 were hosts to experimentally infected ticks. The calves were fed infected milk. The heifer was tested by instillation of the inoculum into the conjunctival sac. A summary of the results of tests so far completed for these experiments follows.

Experiment 1—In November, 1947, infection was readily produced in 2 milk cows, Nos. 1 and 2, following udder inoculation of massive doses of a yolk-sac culture of the Nine Mile strain. Three of the quarters of the udder of cow No. 1 were inoculated as follows: one by way of the teat canal, one via the mammary gland, and one subcutaneously. Only a single quarter of cow No. 2 was inoculated via the teat canal. Milk specimens from all four quarters of both cows were tested at least once a week up to the present time. Milk from uninoculated quarters has not become infectious.

Foremilk or strippings from the single inoculated quarter of cow No. 2 were infectious through the 48th day. All specimens in subsequent tests performed for a period of more than 181 days have been negative.

Tests of similar specimens from the three inoculated quarters of cow No. 1 demonstrated that milk from the quarter inoculated by way of the teat canal was infectious for 17 days; that from the one inoculated via the glandular tissue was infectious for over 200 days; while that from the quarter inoculated subcutaneously remained non-infectious.

Tests of at least 12 specimens each of the blood, feces, urine, and nasal washings, taken from each cow during the first month after inoculation, were consistently negative. Daily rectal temperatures taken for a period of over 2 months did not reveal a significant temperature rise in either of the two animals. Complement-fixing antibodies for Q fever appeared in the serum of both

cows about the beginning of the 2nd week. In subsequent tests, the serum of cow No. 1, which has continued to shed rickettsiae in its milk, has remained positive. In contrast, tests for Q fever antibodies in the serum of cow No. 2, whose milk has been non-infectious since the 48th day, yielded inconsistent and questionable results after about the 60th day. Since that time, the antibody titer of this cow appears to have dropped below a significant diagnostic level.

Experiment 2—In a third lactating cow, a heavy inoculum, consisting of a yolk-sac culture of a California strain (recovered from milk of a naturally infected cow) was introduced into the cervical canal. Pooled aliquots of first-milk samples from the four quarters were tested for infectiousness at 2 day intervals until the 20th day and thereafter at intervals of twice a week.

During the first 18 days postinoculation, only three of ten milk samples were positive, those of the 6th, 10th, and 18th days. However, nearly all specimens taken from the 18th through the 160th days have been positive. Individual milk specimens from each of the four quarters, which had been routinely frozen and stored at —70° C. during this experiment, were thawed and retested separately. These tests revealed that the left front quarter was the only quarter secreting infectious milk.

Specimens of urine, examined for a period of 80 days, were positive on each of the first 8 days, but were negative in all subsequent tests. Specimens of blood taken each day for the first 10 days and thereafter at intervals of at least 5 days were consistently negative. Daily rectal temperatures which were taken for a period of 6 weeks revealed no significant temperature rises.

Q fever antibodies, as detected by the complement-fixation test, appeared in the serum of this cow, and have been consistently present at relatively high levels through the 191st day postinoculation.

Development of infection in the mammary gland of this cow is an interesting observation. The means by which this occurred, however, is a matter of speculation. Contamination of the orifice of the teat by infected urine present on the floor or bedding is possible, since the urine was infectious during the first 8 days postinoculation. The infectious agent in the urine is believed to have been derived by contamination from the inoculum which may have been present in the more external region of the vaginal tract. That infection in the udder was not blood-borne is suggested by the failure to detect the presence of rickettsiae in this material.

Experiment 3—This experiment was planned primarily for the purpose of determining the symptomatology and pathology of Q fever in lactating cows. Six cows were used, 4 of which were inoculated with large amounts of a 10 per cent suspension of an infected yolk-sac culture of the same California strain of *C. burnetii* used in the previous experiment. The remaining 2 served as controls and were injected with a corresponding amount of normal yolk-sac tissue. The inoculum was introduced through the teat canal of the two left quarters of the udder of each cow. Infected cows were sacrificed on the 5th, 11th, 22nd, 63rd days after inoculation. At autopsy, numerous tissue specimens were obtained and fixed for histopathologic study, and portions of the same tissues were stored at —70° C. for subsequent inoculation into guinea pigs. During the period before the animals were sacrificed, samples of milk and blood were tested for infectivity in guinea pigs. Milk was tested three times a week, while the blood was tested each day for the first 10 days, and thereafter three times a week. Detailed laboratory tests, including hematological studies, urine analysis, and chemical analysis of

the milk, were conducted three times a week. Clinical observations were made daily.

C. burnetii was isolated from the blood of all 4 test cows on two or more of the first 5 days, but not from blood taken after this time. Milk from all but one of the injected quarters was infectious from the 1st day after inoculation until the date of sacrifice. In the exceptional case, milk from the left front quarter of the cow sacrificed on the 63rd day became non-infectious on the 44th day. In this same cow, milk from one of the non-inoculated quarters became infectious on the 7th day. Repeated titration in guinea pigs of milk from a single quarter of the cow sacrificed on the 63rd day revealed the presence of rickettsiae in dilutions of at least 10^{-5} and 10^{-4} on the 2nd and 7th days post-inoculation, respectively, and thereafter at 5 day intervals at a dilution of only 10^{-1}.

Following inoculation with *C. burnetii*, an acute mastitis accompanied by a marked systemic reaction was produced. The mastitis during the acute phase was characterized clinically by marked swelling, subcutaneous edema, feverishness, enlargement of supramammary lymph glands, and evidence of pain upon palpation of affected quarters. Microscopic examination revealed a marked increase in the cellular constituents of the milk from infected quarters. The cell count of foremilk rose to a peak of 20 to 30 million per cu. ml. and consisted chiefly of polymorphonuclear leukocytes. During the acute stage of the mastitis, temporary metabolic changes in the activity of the mammary gland were manifested by variations in the content of certain of the constituents of the milk. Among these fluctuations observed were a marked increase in butter fat concentration, increase in chlorides, decrease in lactose, and a marked decrease in total daily milk production. No significant change was noted in the pH of the milk. Recovery from the acute phase of the mastitis was spontaneous. In general, the major symptoms and other changes had disappeared by about the 8th day after inoculation.

The systemic reaction was of brief duration and preceded and accompanied the acute mastitis. It was characterized by a marked pyrexia, slight serous nasal and lacrimal discharges, moderate to severe depression, partial inappetence, infrequent rumination and shallow rumen movements, moderate tachycardia, and a moderate polypnea accompanied only by a definite increase in vesicular murmur. Examination of the blood revealed no marked changes in its cellular constituents, hemoglobin content, or sedimentation rate. No evidence of kidney pathology was revealed by urinalyses conducted at various intervals during the acute and chronic stages of the infection.

Tissues obtained at autopsy and stored at —70° C. were subsequently tested for infectiousness in guinea pigs. Although many of these tests are incomplete, a brief summary will be given of the results to date. Among the specimens tested were the lung, liver, spleen, kidney, heart, brain, adrenal gland, lymph nodes, intestinal tract, and mammary gland. Of those tested from the cow sacrificed on the 5th day, practically all were positive. It should be recalled, however, that the blood of this cow was also infectious on this day. A second cow was sacrificed on the 11th day. Although its blood was negative on each of the 5 days prior to sacrifice, nevertheless, a number of tissues from this cow were positive. Included among the positive tissues were the lung, liver, spleen, the right and left supramammary lymph glands, and the mammary gland tissue taken from the inoculated quarters. Negative results were obtained in a single test of the kidney, heart, and mammary gland tissue taken from the non-inoculated quarters of the udder.

Gross pathology in the sacrificed cows was confined chiefly to the mammary gland and regional lymph glands. In the cow sacrificed on the 5th day, the inoculated quarters were very edematous, with heavy serous accumulations in the subcutaneous tissue of the udder. A marked serous lymphadenitis was noted in the left supramammary and left deep inguinal lymph nodes. Although rickettsiae were recovered from most of the tissues tested to date from this cow, there was little or no pathology observed in other organs. In the cows sacrificed on the 11th and 22nd days postinoculation, the outstanding lesion was a serous lymphadenitis of the left supramammary and left deep inguinal lymph glands. As the infection had become established in the right rear quarter of the cow sacrificed on the 63rd day postinoculation, both supramammary glands were enlarged and edematous.

The 2 control cows in this experiment were used to detect tissue reactions to the normal yolk sac and to detect changes in milk production and composition due to experimental conditions. The normal yolk-sac suspension excited a tissue reaction which was reflected in changes in chemical composition and cellular constituents of the milk. This reaction was of a transitory nature, and changes in production and milk composition were not of the magnitude observed in the infected cows. The control cows remained afebrile and manifested no systemic reaction to the nonspecific mastitis. Weekly injections of milk into guinea pigs and complement-fixation tests of sera of these cows revealed no spontaneous Q fever infection during the course of the experiment.

Experiment 4—This experiment was conducted to determine whether unweaned calves would become infected following ingestion of Q fever infected milk. Infectious milk from cows used in the previous experiment was fed by pail to 2 calves, aged 3 weeks and 3 months, respectively. The milk used was a pool made up of approximately equal portions of infected and normal milk. Each calf received about 6 liters of the pooled milk per day, one until sacrificed, and the other for a period of more than 30 days. The 3 month old calf became febrile on the 13th day after its first infective feeding and was sacrificed on the following day while still febrile. Q fever developed in guinea pigs injected with 4th, 6th, and 12th day blood specimens and an 8th day fecal specimen. Of the tissues obtained at autopsy, only animals injected with the prescapular lymph node and abomasum developed Q fever.

No symptoms were observed in the 2nd calf, although Q fever developed in the guinea pigs injected with 4th and 13th day blood specimens and in those receiving 2nd, 6th, 10th, and 14th day feces. Tests of nearly all fecal specimens taken during the first 20 days, other than those reported above as positive, were rendered valueless by intercurrent bacterial infections of the injected guinea pigs. Tests of urine specimens from both calves were consistently negative.

Based on tests completed to date, it is uncertain whether infection was produced in these calves. The febrile reaction in one of them and the development of Q fever in guinea pigs injected with some of the daily blood specimens from each calf are suggestive of infection in the calves. However, the question of spontaneous infection [11] in the test guinea pigs must be considered. This is suggested by the observations that the blood-injected guinea pigs developing Q fever represented intermittent and not consecutive blood specimens and that guinea pigs receiving only two of the numerous tissues tested from this calf sacrificed while febrile became ill with this disease. In order to demonstrate definitely the presence of *C. burnetii*,

tissues of this calf are being cultured in the yolk sacs of fertile hen's eggs.

Q fever antibodies were not demonstrated in the serum of the surviving calf. This apparent failure to develop specific antibodies may have been due to the young age of this calf.

Additional experiments — Transmission of Q fever to cows by infected ticks of the species *Otobius megnini* Dùges is being attempted. Results to date are indefinite. The only evidence of successful transmission has been the apparent development of Q fever antibodies in the serum of one of the cows. These antibodies appeared about the 3rd week after infestation of the cow with infected ticks, and were present in significant titers from the 20th to 30th days. In later tests the serum antibody titers were low and irregular. Since rickettsiae have not been recovered from blood or milk specimens tested periodically for more than 2 months, it cannot be safely assumed that this cow was infected. Further experiments along this line are to be conducted.

In another experiment, infection of a heifer was attempted by instillation of Q-fever-infected yolk-sac material into the conjunctival sac. The only evidence suggestive of infection was the appearance of specific serum antibodies on about the 7th day postinoculation.

DISCUSSION

Knowledge of the route or routes by which cattle become infected with Q fever in nature is important. Of interest in this respect is the finding that infection is readily produced in the udder of lactating cows following exposure of the mammary gland to *C. burnetii*, and that the rickettsiae are eliminated in milk from the infected quarters for long periods of time. Moreover, attempts to infect cattle by other routes were less definitely successful. The latter results were obtained in heifers, and a single strain of *C. burnetii* was used for inoculation. They are, therefore, inadequate as a basis for comparing the various routes of inoculation for their ease of producing infection. Further tests employing lactating cows and other strains of the rickettsia should be conducted.

In studies [6] of naturally infected cows, clinical symptoms were not observed, and although *C. burnetii* has been isolated from the milk, mammary glands, and supermammary lymph nodes of such animals, it has not been recovered from the blood or other tissues. Whether these observations were made during the acute or chronic stage of the disease is not known. However, that definite clinical symptoms and the presence of *C. burnetii* in the blood and other extramammary tissues may occur during the acute stage of the infection in cows under natural conditions is suggested by the results observed in the experimental disease. In the latter, there was an acute mastitis and a marked systemic reaction for a relatively brief period, yet rickettsiae were recoverable from the mammary gland or its secretion for relatively long periods after inoculation. In addition, rickettsiae were recovered from the blood and numerous other extramammary tissues during the acute stage of the disease. It should be recalled, however, that massive infective doses of *C. burnetii* were employed in these experiments. Whether use of smaller doses more closely approaching conditions expected to occur in nature would yield similar results is not known. Nevertheless, the experimental findings indicate the desirability for further studies under natural conditions.

In the present studies it was found that Q fever rickettsiae were recoverable from the feces of calves ingesting infected milk. It has not been determined whether the presence of *C. burnetii* in this material represents an elimination of the agent following infection of the calf, or merely its passage through the ali-

mentary tract following ingestion of infected milk. Nevertheless, the experimental observation suggests that the feces of calves feeding on infected milk in a natural environment may be concerned with the spread of Q fever among cattle and from cattle to man.

SUMMARY

Q fever infection in lactating cows has been produced consistently by inoculation of *Coxiella burnetii* via the lactiferous duct. Rickettsiae were found in the milk of these cows for long periods of time, in some cases for over 200 days after inoculation. Exposure of the mammary gland to massive doses of a yolk-sac culture of *C. burnetii* excited an acute mastitis accompanied by a marked systemic reaction. These symptoms appeared to be of brief duration, and recovery was spontaneous, yet rickettsiae continued to be shed in the milk. In animals showing these symptoms, rickettsiae were recovered from the blood during the acute period, and from numerous other tissues obtained from cows sacrificed at various intervals up to 63 days after inoculation.

Q fever rickettsiae were recovered from the feces of calves feeding on infected milk. However, infection by this method was not definitely proved.

Experiments involving attempts to infect cattle by other routes of inoculation and by infestation with infected ticks *(Otobius megnini)* are described.

1948 International Red Cross Meeting

A report by Basil O'Connor, President of the American National Red Cross, is now available of the first meeting of the International Red Cross since 1938. This was the 17th International Red Cross Conference held in Stockholm in August, 1948.

The conference is the highest deliberative body of the International Red Cross world and is made up of the International Committee, the 66 national Red Cross society members of the League of Red Cross Societies, and the 72 government signatories to the Geneva Conventions.

The report is available from the American National Red Cross, Washington 13, D. C.

Q Fever

Q Fever Survey in Southwest Texas *

J. V. IRONS, Sc.D., F.A.P.H.A., AND JOSEPH N. MURPHY, JR., M.S.P.H.S.

Texas State Health Department, Austin, Tex.,

AND

A. B. RICH, D.V.M., AND AUSTIN E. HILL, M.D., M.P.H., F.A.P.H.A.

City Health Department, San Antonio, Tex.

AFTER the occurrence of the March, 1946, outbreak of Q fever at Amarillo, Tex., the Texas State Health Department continued to search, particularly by laboratory procedures,[3, 4] for other cases. Because of the relative scarcity of ticks[1] and apparently negative findings on cattle sera[5] in this area it seemed probable that more promising areas for investigation of Q fever in Texas could be found. *Coxiella burnetii* had been demonstrated in pools of ticks collected in southeast Texas in 1937[6] and later at Camp Bullis near San Antonio.[7] Evidence of this infection in packinghouse workers at Fort Worth has also been reported.[8]

In February, 1948, a survey of packinghouse workers at San Antonio, Tex., was begun. It was planned to search for cases of Q fever in several communities in southwest Texas. A search of raw milk samples for *C. burnetii,* the causative agent of Q fever, was also begun.

In much of southwest Texas, the people are to a considerable extent of Latin-American descent, and the Negro population is low. Ranching and diverse farming activities provide occupations for many, and toward the Rio Grande Valley the climate is subtropical and suitable for winter gardening. In the lower Rio Grande Valley citrus orchards are abundant.

Methods of Investigation—Through the coöperation of several local physicians the names of persons who had undergone recent febrile attacks were obtained. Cases of "virus pneumonia" especially were sought. Blood samples were taken by local physicians, or persons were visited, interviewed, and blood samples were obtained by us. Upper respiratory infection constituted the main group of illnesses to be differentiated from Q fever in the spring, while typhus more often was considered in the summer.

The complement-fixation test was of great help in the recognition of Q fever. For the most part the complement-fixation antigen was prepared from the Italian (Henzerling) strain of *C. burnetii,* but the Nine Mile antigen was also utilized on some occasions. Survey bloods from slaughter-house workers and food handlers, as well as milk samples, were obtained in connection with routine tests. All sera were examined in a "screen" test, with a single tube at a 1:10 or 1:20 dilution. All positive tests were repeated quantitatively.[3] The titer was expressed as the highest dilution at which 3+ or 4+ fixation was seen. Blood clots and milk samples to be

tested for *C. burnetii* [4] were stored in duplicate in the frozen state, so that all positive tests could be repeated. Mice, hamsters, or guinea pigs were used for isolation of *C. burnetti.*

Investigation of a Small Outbreak of Q fever in Packinghouse Workers at San Antonio—Almost immediately as a result of the survey in packinghouse workers at San Antonio, a serum showing a very high titer for Q fever was encountered. Upon inquiry the recent occurrence of "virus pneumonia" in workers on the killing floor of one of the major packinghouses at San Antonio was revealed. Three cases, all showing unusually high Q fever titers readily were located. (Cases 3, 4, and 6 in Tables 1 and 3). Case 3 was the general foreman on the killing floor and had become ill December 17. Case 4 was supervisor of the tankage department and had become ill December 18. Case 6 worked in the beef cooler and had become ill December 25. Other members of their families had not been ill. Since the dates of onset were grouped closely it appeared probable that there had been a common source of exposure, and that some of the livestock butchered had been the source. In view of reports [9, 10] on the incubation period in Q fever it appeared that exposures were in late November or early December, 1947. Approximately 80 persons were employed on the killing floor and conceivably a somewhat larger number could have been exposed. During the probable exposure time there had been days when several butchers were absent. None of those ill in December could recall removing ticks from themselves. Hogs, sheep, goats, and cattle had been butchered in late November and early December. Sheep and goat carcasses also passed through the "beef cooler." Since hogs are not handled in the "beef cooler" they were probably not involved. The subsequent serologic survey revealed only one more butcher (case 5 in Tables 1 and 3) who evidently was exposed and became ill December 23. Perhaps others with low titers, as shown in Table 2, were exposed in late November or early December, and had inapparent infections in December, 1947. The low attack rate suggested that the source of infection was not widely disseminated, or perhaps that some workers had been exposed in previous years.

† November, 1947, cases

tonio—The majority of sera were from persons working on or about the killing floors. Practically every slaughter-house in San Antonio was included in the survey. There was a great majority of men in various age groups and mostly with Latin-American names.

Approximately 5 per cent of these sera had a titer of 1:10 or more, and approximately 2.8 per cent had a titer of 1:20 or more, as shown in Table 2.

The individuals with Q fever antibodies mainly were butchers and were scattered among several plants. There was no clear evidence that any particular job on the killing floor was most hazardous. There was some evidence that those few who worked exclusively with hogs were found less often to be reactors. However, it is doubtful that any epidemiological significance could be attached to this observation, because of lack of definite information on workers' activities in relation to exposures.

In the five packinghouses where the higher titers were found, the men were interviewed and absentee records were reviewed for dates of any illnesses during 1947 or 1948. While the results were impossible to evaluate in some instances, it seemed evident enough that two butchers (cases 1 and 2) employed by a second large packinghouse had Q fever in November, 1947. There seemed to be a good possibility that cases 1 and 2 were exposed during the course of their work, perhaps on the same occasion, late in October or early in November, 1947, when both men assisted with butchering cattle, sheep, goats, and hogs. There was no evidence that any others of the 50 men on the killing floor, or others who conceivably were exposed, had been ill in November, 1947.

Serologic Survey of Q Fever in Food Handlers at San Antonio—Five hundred and sixty-five sera from food handlers at San Antonio were examined by the "screen" test for Q fever. This group was similar to the slaughter-house workers' group except for differences in occupation. The group comprised a great preponderance of males of various age groups mainly with Latin-American names. Five hundred fifty-six of these sera were not reactive in the 1:10 serum dilution. Seven showed 4+ at 1:10 and two at 1:20 serum dilution.

Recognition of Scattered Cases of Q Fever in Southwest Texas—Table 1 lists the clinical cases of Q fever which have been found by preliminary investigations in San Antonio and other widely scattered communities in southwest

Texas. The diagnosis of Q fever in each case was based on clinical and confirmatory laboratory findings. The typical clinical history was the same as that described by others.[2, 5, 10] The onset was acute with fever, headache, chills or chilly sensations, and body aches or pains. Chest discomfort was common, and cough was frequently complained of but was not a prominent symptom. Physical examination usually revealed little of note. There was no rash. Chest plates frequently revealed an atypical pneumonic process. The leucocyte count tended to be normal or only slightly elevated. The febrile period usually persisted 1 to 2 weeks and convalescence was prolonged especially in older patients. No deaths occurred.

When the patient was seen in the acute phase of illness, blood was obtained both for antibody test and animal inoculation. Another blood specimen was sought late in the illness or after recovery for possible rise in antibody titer. It was believed that diagnosis was most firmly established by demonstration of a marked rise in antibody titer or recovery of *C. burnetii.* Some patients had recovered when the history notes and blood specimens were obtained, so that the criteria for recognition of Q fever rested on typical clinical history and demonstration of complement-fixing antibodies in high titer, as shown in Table 3.

Since the patients were contacted mainly after the acute phase of illness, the isolation of *C. burnetii* was successful only with case 7. This strain appeared to be typical of the Q fever organism. It caused an enlarged spleen in which the characteristic organisms were demonstrable. Mice developed complement-fixing antibodies in high titers, both with antigens prepared from American (Nine Mile) and Italian (Henzerling) strains of *C. burnetii.*

Epidemiologic Findings on Scattered Cases of Q Fever in Southwest Texas—From Table 1 it is seen that the age of confirmed clinical cases varied from 19 to 78 years. With the exception of case 12 all were men. However, this is of doubtful significance because of the possibility of poor sampling. The cases occurred from November, 1947, to October, 1948, and were still occurring. It seems likely that Q fever has been present for some time. No seasonal in-

* *C. burnetii* was recovered from the clot

cidence is as yet evident. The cases are listed in Tables 1 and 3 in chronological order.

While cases 1 through 6 were butchers, no common epidemiologic factor in cases 7 through 12 is as yet evident. Three cases claimed they drank only pasteurized milk. It is interesting that case 7 claimed he drank only pasteurized milk, but it was learned that the cafe which served the coffee that he and his coworkers at the local postoffice drank several times daily served raw cream with the coffee. Some worked with livestock while others neither worked with, nor lived very near livestock. Working with goats and sheep rather than cattle seemed to be of probable significance in case 8. The possibility of infection from tick bite as a common factor is difficult to rule out, but, with one exception, none could recall recent tick bite before onset of illness. The location of these cases over a wide area is of particular interest.

Demonstration of Complement-fixing Antibodies in Sera from Goats and Sheep—The possibility that case 8 had acquired infection on the W. C. ranch seemed excellent. This man had been working daily with large numbers of goats and frequently with the much smaller flock of sheep on the W. C. ranch. He could not recall seeing any ticks around the sheep or goats. There was a lone cow and her calf on the ranch. Blood specimens were collected from the cow and calf, from three sheep, and approximately in equal numbers from goats raised on the W. C. ranch and from a few truck loads brought to the ranch the previous fall from two other distant ranches. Sera from the cow and calf were negative. It should be mentioned that results of tests on sera from cattle elsewhere have been difficult to interpret since titers found so far have been consistently very low. One of three sera from sheep and eight of fifteen sera from goats, including bearers of each of the three brands, showed the presence of antibodies. Each of the five sera from goats raised on the W. C. ranch showed a titer, ranging from 1:10 to 1:160.

The Demonstration of C. burnetii in Raw Milk and Its Possible Significance in Epidemiology of Q Fever—Raw milk samples were received on ice from several communities in southwest Texas usually in connection with routine tests according to A.P.H.A. Standard Methods. Duplicate tubes on each sample were stored in a deep freeze box until the result of the "screen" test for Q fever on a pool of samples became known. Six to fifteen (with an average of ten) samples from as many dairies were included in a pool. Routine samples were picked up on delivery routes or collected from bulk milk either at the dairy or the processing plant before pasteurization. Specimens collected by us were taken at the dairy either from individual strippings or from pools of small strings of cows. One ml. of milk was inoculated intraperitoneally in each of four mice, or occasionally 2–5 ml. of milk was inoculated in a hamster or guinea pig. In some few instances small doses of penicillin were given. One or two mice were sacrificed at 10 days and their spleens were saved in a deep freeze box. The remainder were bled at 21 or 30 days for complement-fixation test. Passages were not attempted with 10 day spleens as a rule unless a mouse for 21 or 30 day bleeding was not available or showed a titer. Serial bleedings were attempted on hamsters and guinea pigs. Two of seventy tests on pools gave unequivocal positive results. Likewise, unequivocal results were obtained on one sample each from the components of the two positive pools and involved two widely separated dairies in southwest Texas.

DISCUSSION

A small outbreak of Q fever in butchers employed by one of the larger

San Antonio slaughter-houses was encountered as a result of a survey. This outbreak was explosive and occurred in December, 1947. While it seemed evident that the infections were acquired in the course of work, it was impossible to assess the relative importance of cattle, sheep, and goats as the probable source of infection. Since three of the four men ill showed evidence of pneumonitis or atypical pneumonia, the possibility of infection from inhalation was suggested. The low attack rate suggested that exposure was limited or that some workers were immune. The relatively low attack rate perhaps was more typical of the picture in Australia [11] than the outbreaks at Amarillo, Tex., in March, 1946,[1] and Chicago, Ill., in August, 1946.[10]

Results of a survey in slaughter-house workers at San Antonio suggested that the December outbreak of Q fever perhaps was not unique but merely was the most recent. In another slaughter-house two cases had occurred in November, 1947. It seemed probable that Q fever had been occurring for quite some time, as was found at Fort Worth, Tex.[8] Many of those having antibodies for Q fever lacked a history of illness particularly suggestive of Q fever and it seemed likely that several had undergone mild or inapparent attacks. Many of these butchers have followed this occupation for years and perhaps had Q fever antibodies in past years which in some instances had become negative.[5] The percentage of sera showing antibodies was significantly greater in slaughter-house workers than in food handlers at San Antonio.

The list of cases of Q fever shown in Table 1 is undoubtedly only a very small fraction of the total number of cases which have occurred in southwest Texas. Most of these persons were patients of a few physicians who were especially curious, or the diagnosis was made more or less accidentally. Undoubtedly physicians will become increasingly aware of the possibility of Q fever and will make increasing use of laboratory facilities to aid in the diagnosis of this disease.

Frequent failure to obtain a history of intimate contact with livestock was somewhat confusing, however, many persons perhaps would not recall occasional intimate contacts with livestock. It seems probable that case 8 had acquired the infection through working with goats or sheep rather than cattle. The finding of *C. burnetii* in raw milk confirms the report of Huebner and others,[12] in California, and certainly suggests the possibility of infection through ingestion of contaminated milk. The possibility of survival of *C. burnetii* in improperly pasteurized milk has not as yet been investigated.

SUMMARY

1. Six cases of Q fever which occurred among butchers in two slaughter-houses at San Antonio, Tex., in November-December, 1947, were found as a result of a survey.

2. Approximately 5 per cent of slaughter-house workers' sera at San Antonio, Tex., showed complement-fixing antibodies for Q fever. Approximately 1.6 per cent of food handlers' sera at San Antonio showed complement-fixing antibodies.

3. Six cases of Q fever were found in widely scattered communities in southwest Texas.

4. *C. burnetii* was identified in raw milk samples from two dairies in southwest Texas, but the significance of this finding was not determined.

5. Complement-fixing antibodies were found in sera from sheep and goats on a ranch where a case of Q fever occurred.

Frontal Attack on Cerebral Palsy

The first national conference on cerebral palsy was held in New York January 6–11. Attended by 1,500 persons, it explored the medical and social aspects of the ailment and laid the groundwork for a national program similar to those for tuberculosis, infantile paralysis, heart disease, and cancer. Among the facts brought out by the conference are that there are about half a million victims of the crippling disease in the country, and that 75 per cent of them can be rehabilitated and taught to gain the use of their muscles.

The preliminary framework for a National Foundation for Cerebral Palsy has been established through Leonard Goldenson, Vice-President of Paramount Pictures and father of a five year old sufferer from cerebral palsy. Three of the other founders, including Albert Felmet, Jr., President of the New York State Cerebral Palsy Association, are parents of cerebral palsied children.

The program for which the foundation plans to work includes federal aid for adequate special educational training for the handicapped; Congressional appropriations for improved local public health services; expansion of state school health activities and crippled children's services; formation of a national research center to work on causes and management of cerebral palsy; federal, state, and local aid for professional training to combat the affliction; and the expansion of citizen associations in the field.

The foundation has temporary offices in the New York Academy of Medicine Building, 2 East 103rd St., New York City. Arthur Larschan, first Vice-President of the New York Group, is serving as its temporary chairman.

Q Fever

Complement-Fixing Antibodies with C. *burnetii* Antigens in Various Geographic Areas and Occupational Groups in the United States *†

ELIAS STRAUSS, M.D., AND S. EDWARD SULKIN, PH.D., F.A.P.H.A.

Department of Bacteriology and Immunology and the Department of Medicine, Southwestern Medical College, Dallas, Tex.

Q FEVER is world-wide in its distribution. Within a decade since its recognition in Australia [1] the disease has been identified in the United States, the Mediterranean area,[2] Switzerland,[3] Germany,[4] and Panama.[5] Although a few sporadic cases had been recognized previously,[6, 7] the first epidemic occurring under natural conditions in this country was reported from Amarillo, Tex., in March, 1946, and involved persons employed in a stockyard and meat packing plant.[8] In August, 1946, a second natural epidemic, also involving packinghouse workers, occurred in Chicago.[9] In the fall of the same year an endemic focus of Q fever was discovered in Los Angeles County, and in the course of the subsequent year approximately 150 cases were identified.[10, 11]

The mode of transmission of Q fever to human beings has not been defined satisfactorily nor has its natural reservoir or vector been clearly identified. In Australia [12] and in the United States [13, 14] ticks infected with *Coxiella burnetii* have been found in nature and in sporadic instances have been responsible for the human disease.[7, 15] Investigations of the epidemics in this country and in the Mediterranean area, however, have not incriminated ticks or other arthropods as the vectors of Q fever. Two of the 3 American epidemics have involved packinghouse and stockyard workers but the manner in which infection took place was not established. In the Los Angeles County outbreak the investigators pointed to a relationship with dairy cows, and indeed milk from such animals was found to be infected with *C. burnetii*.[10] However, it was not established that infection took place through the ingestion of milk. At present, no single explanation seems adequate to satisfy the varying circumstances under which the disease has been recognized.

A complement-fixation test has been devised for the detection of antibodies against a *C. burnetii* antigen prepared from the infected yolk sacs of embryonated hen's eggs.[16] Such antibodies have been found to persist in sera following naturally acquired infections for as long as 17 months.[17]

In view of these facts, it appeared desirable to undertake a serological survey to determine the frequency with which antibodies against a *C. burnetii* antigen occurred in different geographic areas and among different occupational groups. Sera from packinghouse workers and dairy workers were selected because of the previous occurrence of Q

---

* Presented at a Joint Session of the Epidemiology and Laboratory Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 12, 1948.

† This study was aided by grants from the Lederle Laboratories Division of the American Cyanamid Company, Pearl River, N. Y., and the Rose Lampert Graff Foundation, Los Angeles, Calif.

fever among such workers. In addition, samples of sera from the general population in widely separated areas of the country were secured. A preliminary report of the occurrence of antibodies against *C. burnetii* in packinghouse workers in Fort Worth, Tex., has already been presented.[18] In this report the results of complement-fixation tests on 5,470 sera are summarized as follows: packinghouse workers at Fort Worth, 1,433 sera; packinghouse workers at Austin, Minn., 150 sera; routine serological laboratory specimens from Amarillo, Tex., 175 sera; routine serological laboratory specimens from Dallas, Tex., 1,033 sera; routine serological laboratory specimens from Boston, Mass., 965 sera; routine specimens from prospective blood donors from Dallas, 798 sera; specimens from dairy workers in the Dallas milk shed, 350 sera; and, finally, routine serological laboratory specimens from Portland, Ore., 566 sera (the latter collected and tested for antibodies by Dr. A. W. Frisch and the results included in this report with his kind permission). The results have been analyzed with regard to the specificity of the serologic tests employed, and for the information they yield with regard to the frequency of occurrence of antibodies for *C. burnetii* in the United States.

METHODS

Serum specimens were transported to this laboratory within 2 days after collection if obtained locally, or by air express from distant points, and were stored in a deep freeze cabinet until tested.

The Q fever antigen was prepared from the yolk sacs of embryonated eggs infected with a strain of *C. burnetii* (American Nine Mile) isolated in Montana in 1935.[13] The antigen was a washed rickettsial suspension prepared by a combination of ether extraction to remove fats and repeated centrifugation cycles to remove extraneous proteins and fats.[19] Two lots of antigens were used (Q9M-5-16 and Q9M-4-26). Almost all sera reacting with *C. burnetii* antigens were also tested with a yolk sac antigen prepared from uninfected embryonated eggs.*

Complement-fixation tests were performed according to the method of Bengtson.[16] The antigen was diluted 1:32 (2 units). Complement was titrated in the presence of antigen, and 2 units of complement were used in the tests.

Serial twofold dilutions of inactivated sera were made, using a single pipette for each serum specimen. The hemolytic system consisted of equal volumes of 2 per cent sheep erythrocytes and amboceptor made up to 2 units. In performing the tests, 0.2 ml. of diluted antigen, serum, and complement were added to each tube, mixed thoroughly, and stored at icebox temperature for 18 hours. Sensitized sheep erythrocytes (0.4 ml.) were then added, and the tubes held at 37° C. in a water bath for 1 hour or until control tubes showed complete hemolysis. Appropriate serum and antigen controls, as well as known positive and negative human and guinea pig sera, were included in each series of tests. The endpoint was read as the highest serum dilution showing at least 3+ fixation.

All sera were examined in a "screen" test using 2 dilutions of serum: 1:8 and 1:16. Sera having titers of 1:16 in the "screen" test were retested in twofold serial dilutions from 1:8 to 1:512 or greater.

Serological Tests for Syphilis—A variety of serological tests for syphilis were performed. Approximately 40 per cent of the sera were tested in one Dallas laboratory (Parkland Hospital) by routine Kahn and Kline tests, Kolmer type

* The *C. burnetii* and normal yolk-sac antigens were prepared in the laboratories of Dr. Herald R. Cox, Lederle Laboratories Division, American Cyanamid Company; generous supplies were made available by Dr. Cox.

complement-fixation tests, and by the use of cardiolipin antigens. Another 20 per cent were tested by similar techniques, including the use of cardiolipin antigens in the laboratory of the Fort Worth Health Department. The sera from Boston were tested by the Hinton test in the laboratory of Dr. William A. Hinton. The remainder were tested by the Amarillo Health Department and by Dr. A. W. Frisch by the usual Kline and Kahn techniques.

RESULTS

The results of the studies are presented in 2 parts: first a description of the origin and composition of the various groups from which serum specimens were obtained and the antibody titers found; and second, data bearing on the specificity of the test.

Fort Worth: packinghouse workers—Serum specimens obtained from 1,433 persons employed in the actual handling and processing of meat and meat products in one large and several small packinghouses at Fort Worth, Tex., were tested for complement-fixing antibodies against *C. burnetii* antigen. A preliminary report of this study has been published.[18] The data will be summarized here for comparison with the results of other studies. The specimens were collected during May and June, 1947, by the Fort Worth Health Department for the performance of routine serological tests for syphilis required of food handlers. The majority of persons tested were adult white males but complete data on age, sex, and racial composition of the total group were not available.

Among the entire group of 1,433 sera, 8 per cent exhibited complement-fixing antibodies in a titer of 8 or more. The titers are recorded in Table 1. Seventeen serum specimens (1.2 per cent) had titers of 64 or more; among these, 10 had a titer of 64, 2 a titer of 128, 3 a titer of 256, and 2 a titer of 512.

It was not possible to interview the individuals with high titers of antibodies against *C. burnetii* or to obtain information with regard to illness. The plant physicians were unaware of the occurrence of an epidemic or of an unusual number of cases of unexplained illness. Analyses of the specific work performed by those with elevated antibody titers did not suggest a correlation with any particular job or department in the plants.

Minnesota: packinghouse workers—From November, 1947, to January, 1948, 150 serum specimens were received from a large meat packing plant in Austin, Minn. The sera were obtained from employees who came to the plant dispensary for first aid and for various medical complaints. Specimens were collected only from those employees who actually handled meat and meat products within the plant. All but 6 were white males between 20 and 61 years of age. One-third of the group had been employed at the plant for more than 15 years each, and 90 per cent of the group had been employed there for more than 5 years. In contrast with the results among packinghouse workers in Fort Worth, only one serum (0.7 per cent) in the Minnesota series exhibited complement-fixing antibodies with *C. burnetii* antigen, and then only in a titer of 8 (Table 1).

Amarillo: Serological laboratory—In August, 1947, 175 serum specimens were obtained from the Amarillo (Texas) City Health Department after routine serological tests for syphilis had been performed. Most of the sera were obtained from adult white males but the specific age, sex, and racial composition of the group was not available.

Fourteen sera (7.9 per cent) exhibited titers of 8 or more (Table 1). Both of the individuals with high titers (64 and 1,024) were subsequently found to have been ill with Q fever during the stockyard epidemic of March, 1946.[8] Histories of illness were not available from

the other 12 individuals with titers of 8 or more.

Dallas: serological laboratory—During July, 1947, 1,033 consecutive serum specimens were obtained from the serological laboratory at Parkland Hospital, Dallas. All sera were originally submitted for serological tests for syphilis. Approximately 60 per cent of the sera were obtained from the venereal disease clinic and the remainder from inpatients, prospective blood donors, and patients attending other clinics at the hospital. Almost all persons were adults, 43 per cent were male, 57 per cent female, 33 per cent were white, and 67 per cent were Negroes.

One hundred and five sera (10.2 per cent) were found to have complement-fixing antibody titers of 8 or more against *C. burnetii* (Table 1). However, only 11 sera had titers of 32 or more and only 4 had titers of 64; none had titers in excess of 64. The sex and racial distribution of those with titers of 8 or more was the same as for the series as a whole. The clinic or hospital records of these patients were reviewed. Several gave a history of pneumonia. No clear evidence of an illness which might have been Q fever was obtained, but the records were considered inadequate for the purpose.

Boston: serological laboratory—During October and November, 1947, 965 sera were received from the Wassermann Laboratory of the Massachusetts State Department of Health and were tested for complement-fixing antibodies against *C. burnetii*. These blood samples had been submitted from various sources for routine serological tests for syphilis. Almost all were from adults, 64 per cent were from females, and 98 per cent were from white persons.

Eleven of the 965 sera (1.1 per cent) contained antibodies for *C. burnetii* in a titer of 8 or more; the titer was 8 in one instance, 16 in 8, 32 in 1, and 64 in 1 (Table 1). The sex and racial distribution of these 11 persons conformed to the distribution in the series as a whole. A questionnaire inquiring into occupation, history of "virus" pneumonia, and service in the Mediterranean area during World War II was answered by 7 of the 11 positive reactors. One whose serum had a titer of 32 had "virus" pneumonia in 1943; another with a serum titer of 16 had pneumonia in the winter of 1947. The individual whose serum showed a titer of 64 denied any illness in the past 2 years.

Dallas: blood donors—Because of the high incidence of positive reactors with both *C. burnetii* and syphilitic antigens in the first Dallas series, another series of different composition was obtained. From December, 1947, to March, 1948, consecutive samples of blood were obtained from prospective blood donors, the samples being submitted for routine serological tests for syphilis. (The latter were performed in the same laboratory as the first Dallas series.) A total of 798 blood samples were obtained. Two-thirds of the donors were white, and one-third colored; 80 per cent were males and 20 per cent females.

Seventeen (2.1 per cent) of this group had complement-fixing antibodies; 9 had a titer of 8, and 8 a titer of 16 (Table 1). The racial and sex distribution for these persons was the same as for the whole group. A history of occupation or of illness was not available.

Dallas: dairy workers—A total of 350 blood samples was obtained during March and April, 1948, from dairy and dairy plant workers in the Dallas area. One hundred and one of these actually lived and worked on dairy farms in close association with dairy cows. All but one were white adults, from 16 to 69 years of age; 87 were males and 14 females. All but 14 per cent had been so employed for more than 1 year; 60 per cent for more than 5 years; and 40

per cent for more than 10 years. In this group, only one individual's serum fixed complement with *C. burnetii* antigen in a dilution of 8 or more; in this person, the titer was 32.

In addition to the farm workers, 249 blood samples were secured from employees of dairy plants, the majority of whom were white males. Approximately two-thirds of the total were indoor plant workers engaged in various phases of the pasteurization and packaging of milk and milk products; the remainder were mostly route salesmen. Of this group of 249, 6 (2.4 per cent) reacted positively with *C. burnetii* antigen. Three had a serum titer of 8, 2 a titer of 16, and one a titer of 32. Combining both groups of dairy workers, 7 of 350 (2.0 per cent) reacted positively; the highest titer being 32 in 2 persons (Table 1).

Oregon: serological laboratory — Through the courtesy of Dr. A. W. Frisch it was possible to include the results on 566 specimens submitted to several serological laboratories in Portland, Ore., for routine serological tests for syphilis. Dr. Frisch's technique in testing for antibodies to *C. burnetii* was similar to that used here with 2 exceptions: (1) the serum dilutions were 10, 20, etc., instead of 8, 16, etc., and (2) the Henzerling instead of American (Dyer) strain of *C. burnetii* was used as antigen. The results are recorded in Table 1. Ten of 566 samples (1.8 per cent) reacted positively in a titer of 10 or more. Six had a titer of 10, and 4 a titer of 20. These results are recorded in Table 1, under the columns for titers of 8 and 16 respectively.

SPECIFICITY OF THE SEROLOGICAL TEST

Relation between STS and serum reactivity with C. burnetii—The unexpectedly high (10.2 per cent) frequency of serum reactors to *C. burnetii* antigen among the 1,033 specimens in the original Dallas series prompted further analysis of the data. The results clearly revealed a significant correlation between a positive or doubtful STS and reactivity in the complement-fixation test with *C. burnetii*.

Of the 1,033 sera tested, 38.4 per cent yielded positive (27.1 per cent) or doubtful (11.3 per cent) tests for syphilis. However, in the group of 105 sera yielding positive complement-fixation tests with *C. burnetii* antigen, 60 per cent also had positive or doubtful tests for syphilis. This relationship, expressed according to the titers of rickettsial antibodies, is shown in Table 2. The whole series was then divided into 2 groups according to whether the STS was negative (636 sera) or positive or doubtful (397 sera), and the number and percentage of reactors with the rickettsial antigen calculated (Tables 3 and 4). A fourfold table relating positive and negative reactivity with *C.*

burnetii with the results of the tests for syphilis, in the whole series, yielded a chi square value of 23 and the highly significant P value of less than 0.01.

In the Fort Worth series 4.0 per cent had positive or doubtful STS; among the 114 sera in this series which reacted positively with *C. burnetii,* 6 (5.4 per cent) also had positive or doubtful STS. The rickettsial complement-fixation titers among these 6 individuals with positive or doubtful STS were: 8 in 2 instances, 16 in 3, and 512 in 1. The relationship between the 2 serologic tests could be fortuitous and the P value was not statistically significant.

In the Amarillo series, 5.7 per cent of the sera yielded positive or doubtful results in the STS. Among the 14 sera which fixed complement in the presence of the rickettsial antigen, 2 (14.3 per cent) also had positive STS. The titers for *C. burnetii* in both of these sera were 16. The series is too small for statistical analysis although the results suggest more than a coincidental relationship between the two serologic tests.

Among the 101 specimens from dairy farmers in the Dallas milk shed, the only serum which reacted positively with *C. burnetii* (titer 32) also yielded a doubtful reaction in the serologic tests for syphilis. In all of the other series studied, the relationship between reactivity with syphilitic antigens and the rickettsial antigen could be explained by chance association. Likewise, statistical analysis of all series combined (excluding the original Dallas series) yielded a P value which was not significant.

Reactions with normal yolk-sac antigen—The possibility was considered that some of the sera which reacted in the presence of *C. burnetii* yolk-sac antigen might also fix complement in the presence of normal, uninfected yolk sacs. Accordingly an antigen was obtained from Dr. Herald R. Cox consisting of the yolk sacs of normal embryonated hen's eggs prepared by the same technique as the rickettsial yolk-sac antigens. Almost all sera which reacted in a titer of 8 or more with rickettsial antigen in the "screen" test were again tested with normal yolk-sac antigen and with *C. burnetii* antigen. In no instance was a positive reaction encountered with normal yolk-sac antigen.

Effect of temperature of inactivation—In further attempts to determine the specificity, or lack of specificity, of serological reactions with *C. burnetii,* a number of tests were performed at various temperatures of inactivation of the sera. Inactivation was carried out at 56° C. for 10 minutes and at 65° C. for 15 minutes on sera which in the usual tests reacted with both syphilitic and rickettsial antigens. There were no significant differences in the rickettsial complement-fixation titers at different temperatures of inactivation, nor was complement-fixation demonstrated with the normal yolk-sac antigen under these circumstances.

Reproducibility of results—Sera reacting positively with *C. burnetii* antigen were retested at least once and in many instances several times. Titers tended to fall off, and the sera to become anti-complementary, with repeated thawing and freezing incidental to storage and retesting. The results of repeated tests, however, conformed to the usual reproducibility of most quan-

titative complement-fixation tests. Unusually discrepant results were not encountered. Two different lots of antigen were employed and many of the positive sera were tested with both antigens, with similar results. A group of positive and negative sera were also tested in the laboratory of Dr. Cox with results corresponding well with those obtained in this laboratory.

Persistence of antibodies — Complement-fixing antibodies persist for many months following proved natural infection with Q fever.[17] It was, therefore, of interest to determine the antibody titers on serum specimens obtained several months after the original samples. Nonspecific reactivity might be expected to fluctuate or disappear while true antibody might be expected to persist or decline in titer slowly. Second blood samples were obtained in 42 instances from Fort Worth meat packers 4 months after the original bleedings; in all cases a titer of 8 or more was demonstrated. A comparison of the titers of original and second specimens is shown in Table 5. A distinction is made between a titer of 0, indicating a complete absence of complement-fixation in a final serum dilution of 8, and a titer of <8, indicating some fixation of complement but less than a 3+ reading. With a few exceptions the titers declined in the 4 months interval. However, the falls in titer were moderate and uniform at all initial levels. Of 42 persons, with titers of 8 or more, 23 still had titers of 8 or more 4 months later.

In the series from the Boston laboratory, second samples of blood were obtained from 3 individuals, 1 month, 2 months, and 6 months after the original specimens. Two with original titers of 16 still had titers of 16, 2 and 6 months later; while a third with an original titer of 64 had a titer of 32, 1 month later. One of the positive sera was originally also positive in the serologic test for syphilis. The second specimen from this subject, while exhibiting the same titer with *C. burnetii* antigen, was negative in the test for syphilis.

Hospital patients with suspected Q fever and miscellaneous diseases—Acute and convalescent phase (3–4 weeks after onset) blood specimens were obtained from 22 patients suspected of having Q fever. Seven patients had pulmonary infiltrations without evidence of bacterial pneumonia. The remainder were sporadic cases of acute febrile illnesses in which the usual studies did not establish a specific diagnosis. In addition, acute and convalescent blood was obtained from 2 cases of infectious mononucleosis. Single blood samples were also obtained from 22 cases of lymphopathia venereum. Complement-fixation tests with *C. burnetii* antigen were negative in all instances, with one exception:

A 20 year old male white college student with previous Army service in Korea was hospitalized with fever and pulmonary infiltration. Malaria was proved by examination of blood smears. On appropriate antimalarial chemotherapy, fever and the pulmonary lesion disap-

peared within a week. Blood serum taken 5 days after onset was anticomplementary; the STS at this time was negative. Blood serum taken 12 days after onset fixed complement with *C. burnetii* in a titer of 16, but another sample taken 6 weeks after onset had a titer of less than 8. It is difficult to evaluate the significance of these serological reactions. The relatively low titer and its rapid fall suggested a nonspecific reaction, possibly related to malaria.

In the original Dallas series were included the results of complement-fixation tests on sera of 129 hospitalized patients. The single blood samples available were obtained, in general, within a few days after admission to the hospital. These patients, representing consecutive admissions to all services of a general hospital, suffered from a wide variety of illnesses. Approximately one-third had acute or chronic infections and many were febrile at the time blood was drawn. No evident correlation was found between the diagnosis established during hospitalization and the complement-fixation titer against *C. burnetii,* with the exception, already mentioned in this series, of the association between positive STS and reactivity with the rickettsial antigen.

DISCUSSION

A considerable body of evidence attests the diagnostic significance of a rising titer of complement-fixing antibodies for *C. burnetii* following an illness. Such antibody responses have been demonstrated following illness proved to be Q fever by recovery of the rickettsiae from the bloodstream.[2, 8] It is also established that such antibodies persist for prolonged periods of time.[16, 17]

On the other hand, there are few data by which can be assessed the specificity and diagnostic significance of complement-fixation with *C. burnetii* antigen of single serum specimens obtained without knowledge of the clinical history, from presumably well persons. To our knowledge, no large serological surveys employing this test have been recorded. Cross-reactions with other rickettsial antibodies do not occur in Q fever,[16] but systematic studies of possible nonspecific reactions or cross-reactions with other diseases have not come to our attention. Moreover, the data are not available which would permit one to regard any particular serum titer as being significant of a previous attack of Q fever.

In the original Dallas series the incidence of complement-fixing antibodies to *C. burnetii* was 15.9 per cent among persons with positive or doubtful serologic tests for syphilis and 6.6 per cent among those with negative tests for syphilis. Since this difference was not likely to arise by chance, some other explanation must be sought. Possibilities to be considered include: (1) false positive serologic tests for syphilis occurred in the presence of antibodies for *C. burnetii;* (2) some factor of selection in the series, such that *C. burnetii* antibodies were more common in persons who also had syphilis; and (3) nonspecific complement-fixation occurring with *C. burnetii* yolk-sac antigen in the presence of syphilis.

The occurrence of false positive serologic tests for syphilis in persons with complement-fixing antibodies for *C. burnetii* seems unlikely. Three-fourths of the 105 persons with rickettsial antibodies were attending a venereal disease clinic. In almost all instances the diagnosis of syphilis was well established. Most patients had been seen originally with primary or secondary syphilis; several had neurosyphilis; and in 9 instances Kahn titers of 64 or more units were present at the time of this study. Available evidence indicates, therefore, that most of these subjects had syphilis and not false positive serologic tests for syphilis.

That the observed relationship between serologic tests for syphilis and

complement-fixation with *C. burnetii* was due to some factor of selection in the group studied, cannot be supported or denied with assurance. The race and sex distribution of the *C. burnetii* reactors was the same as for the group as a whole. Most of them were urban dwellers. The females worked most often as domestics, the males as unskilled laborers. Considering the clientele of the clinic it seems reasonable to believe that positive and negative reactors to *C. burnetii* antigen as well as those who had positive or negative serologic tests for syphilis all came from the same general environment and engaged in the same occupations. Specific data to substantiate these assumptions are not available.

The possibility of nonspecific complement-fixation with *C. burnetii* antigen in sera with positive or doubtful serologic tests for syphilis should receive serious consideration. Previous studies have indicated that other yolk-sac antigens may also fix complement with syphilitic sera.[20, 21] The present results cannot be explained satisfactorily, but they raise a question with regard to the specificity of this test which can only be settled by further investigation.

If it is assumed that the presence of complement-fixing antibodies for *C. burnetii* indicates previous infection with this organism one must conclude that this survey disclosed a considerable number of otherwise unrecognized cases of Q fever. This assumption seems particularly strong in connection with the results obtained in the packinghouse workers at Fort Worth. Not only was the total incidence of positive serological reactions high (8 per cent), but the incidence of high titers was also considerable (2.3 per cent had titers of 32 or more). The persistence of the antibodies for a period of 4 months further supports the belief that they indeed represented infections with Q fever. The fact that an epidemic was not recognized may be explained on the assumption that the illnesses were sporadic, that they masqueraded under more banal clinical labels, or that they were subclinical. All of these possibilities are known to occur with Q fever.

The serological results obtained among meat packers at Fort Worth thus represent the third instance in this country in which Q fever has been identified in packinghouse workers. However, as Shepard had already pointed out, the infectious agent must reside rarely, not commonly, in such an environment.[9] Among the Minnesota packinghouse workers the incidence of positive reactors for *C. burnetii* was negligible, and yet these workers had had contact with many thousands of animals over the course of years.

Unlike recent experiences in Los Angeles County, the incidence of rickettsial antibodies among dairy workers in the Dallas area was not higher than in a sample of the general population. Many of the persons studied had had years of close association with dairy cattle. As with meat packers, one must conclude that the epidemiological association between Q fever and occupation or environment seems to be an intermittent, and not a constantly operating phenomenon.

In one of the studies of the Los Angeles outbreak recently reported, data are presented indicating that 1.8 per cent of a group of sera with negative STS from individuals residing in the milk shed area exhibited complement-fixing rickettsial antibodies in a titer of 8 or 16.[11] In the present study, a similar incidence of antibodies in low titer was also found in Dallas, Boston, and Oregon, areas where Q fever has not been recognized clinically. In Texas (Dallas, Amarillo, and Fort Worth) the incidence of antibodies for *C. burnetii* appears to be higher than elsewhere. These data may suggest that Q fever

may be widely distributed throughout the United States.

A question has arisen in recent publications as to the selection of the proper strain of *C. burnetii* for use as an antigen in complement-fixation tests. Patients infected in Italy with Q fever developed complement-fixing antibodies to the Italian (Henzerling) strain but not to the American (Dyer) strain.[2] The latter has been said to be a less sensitive antigen than the former.[22] Immunized guinea pigs developed an early rise in titer to the Henzerling strain, and a delayed response to the Dyer strain, but 2 months later the titers became comparable. Similarly, human beings immunized with vaccines prepared with these strains exhibited better antibody responses with the Henzerling than with the Dyer strains.[23] It must be pointed out however, that successful, and diagnostically useful, complement-fixation tests were performed with the Dyer strain in the investigation of the Amarillo epidemic,[8] and in a follow-up study of this epidemic, carried out at this laboratory, dealing with the persistence of antibodies.[17] The problem of the choice of antigens cannot be considered settled. The present study was conducted entirely with the use of the Dyer strain and no comparisons with the 2 antigens could be made. If the results of the studies mentioned above are applicable to the present circumstances it may be implied that an even greater number of sera would have fixed complement had the Henzerling strain been employed.

SUMMARY

1. Complement-fixation tests were performed in 5,470 sera using yolk-sac antigen of *C. burnetii* (American Nine Mile strain). The sera were obtained from persons residing in Massachusetts, Minnesota, Oregon, and Texas. Sera were obtained from meat packers in Fort Worth, Tex., and Austin, Minn., and from dairy workers in the Dallas area.

2. Sporadic instances of complement-fixation, which may indicate Q fever, were found in sera from all geographic areas included in the study, suggesting that Q fever may occur in low incidence throughout the country. Evidence for its occurrence in appreciable numbers among packinghouse workers in Fort Worth was presented. The evidence also suggested that residents of the southwestern part of the United States may have a higher incidence of complement-fixing antibodies with *C. burnetii* than in other areas of the country.

ACKNOWLEDGMENTS—The serological studies in this laboratory were performed by Elizabeth L. Watson and Helen Leonard. Grateful acknowledgment is made to: Drs. Harold M. Williams and D. A. Reckie for supplying serum specimens from Fort Worth, and to Miss Edith Mazurek for performing STS on these specimens; Dr. William A. Hinton for supplying the serum specimens from Boston, performing STS on these sera, and for supplying clinical data and second specimens on positive cases; Dr. H. R. Allen, for supplying sera from Austin, Minn.; Jack Wyatt for sera from Amarillo and STS on these sera; Dorothy Lee for supplying sera from Dallas and for STS on these and other sera; Earl Sudderth and his staff for assistance in collecting sera from Dallas dairy workers; and Dr. A. W. Frisch of Portland, Ore., for generously permitting the inclusion in this report of data obtained in his laboratory.

We also wish to acknowledge the generous assistance of Dr. Herald R. Cox in supplying the antigens used in this study and in testing selected sera in his laboratory.

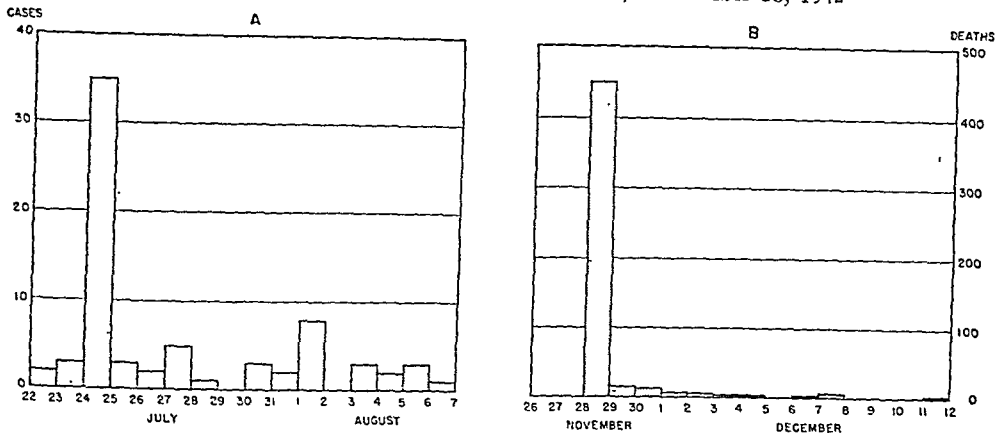
The Epidemiology of Accidents*

JOHN E. GORDON, M.D., F.A.P.H.A.

Professor of Preventive Medicine and Epidemiology, Harvard School of Public Health, Boston, Mass.

EXISTING rates for deaths from accidents and violence remain numerically at almost the identical level of 1900, 88 per 100,000 population in 1900 and 88 in 1946. The relative position among public health problems is at a higher level,[1] since these conditions have advanced as a cause of death in the United States from sixth place in 1900 to third in 1946.

Industry and various governmental agencies have given much attention to the accidents that occur in the places where men work, in public areas, and in relation to motor cars. Accidents in homes outdistance any other class in the losses they cause, whether judged by deaths, by the permanent defects that follow, or by temporary disability. Like all programs for the prevention of mass disease and injury, that directed toward accidents is necessarily a team effort involving a number of agencies and a variety of disciplines. Although health departments have an obligation in all accident prevention, a better record for home accidents is believed to depend largely upon what health departments do in that field. If home accidents are primarily a public health problem, then that problem is reasonably to be approached in the manner and through the technics that have proved useful for other mass disease problems. This includes first an epidemiologic analysis of the particular situation, an establishment of causes, the development of specific preventive measures directed toward those causes, and finally a periodic evaluation of accomplishment from the program instituted.



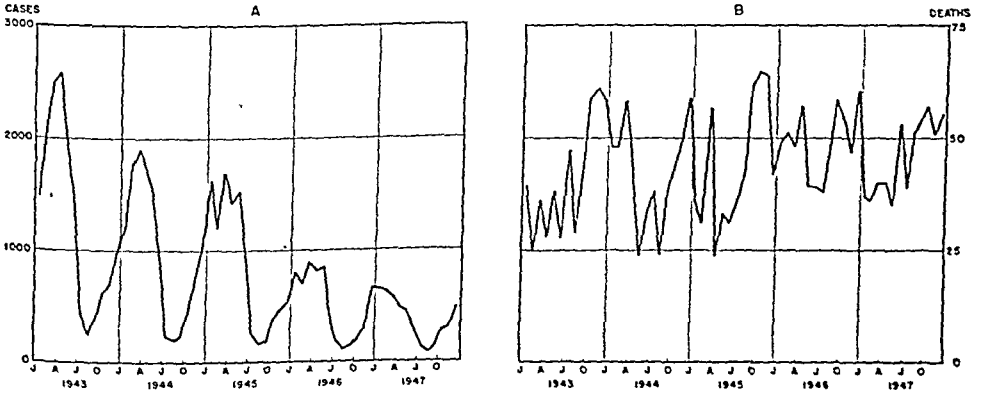
No need exists in these days to trace the way in which the epidemiologic method has extended from its original restriction to the communicable diseases, to a broad application to mass disease of man; to cancer, diabetes, congenital anomalies, and many others. It is not so generally appreciated that injuries, as distinguished from disease, are equally susceptible to this approach, that accidents as a health problem of populations conform to the same biologic laws as do disease processes and regularly evidence a comparable behavior. This is readily indicated by an initial comparison of representative diseases and injuries according to frequency distributions in time, an epidemiologic characteristic of established value in separating one mass disease from another, and in distinguishing kinds of behavior.

MOVEMENTS OF DISEASE AND INJURY ACCORDING TO TIME

The point epidemic is perhaps the most arresting of all distributions in time, that circumstance where a sharp aggregation of cases occurs within a brief interval as the result of a single agent acting during a prescribed and limited time (Figure 1). A circus train[2] backed up to a standpipe in the Pittsburg railroad yards, filled its tanks with untreated river water and some two weeks later typhoid fever exploded

* Presented before a Joint Session of the Public Health Education and Vital Statistics Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., Nov. 12, 1948.

FIGURE 1—Point Epidemic: (a) Typhoid Fever in a Circus,[2] July 22 to August 6, 1934; (b) Cocoanut Grove Nightclub Fire, Boston,[3] November 28, 1942



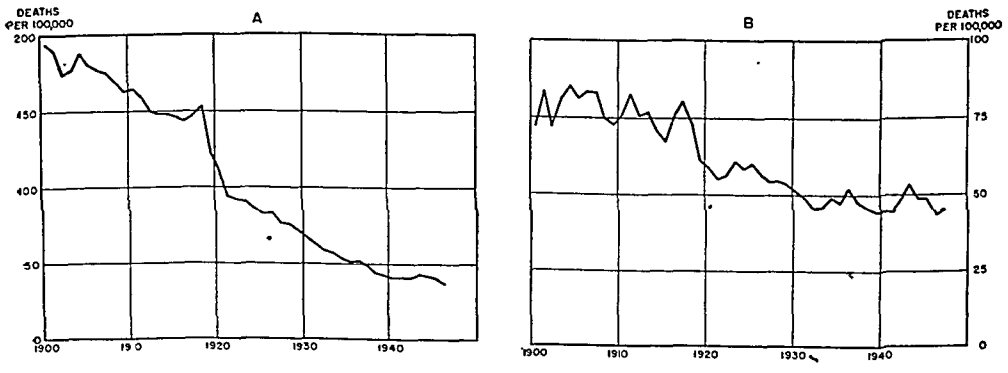
sharply as the troupe played Dayton, Ohio. The deaths from accidents which occurred in the 1942 Cocoanut Grove night club fire in Boston[3] were of the same order, the result of a single causative agent striking once and leading to an explosive outbreak with subsequent scattered deaths due to a more resistant host or a lesser activity of the agent. The result of a Florida hurricane would serve equally well in illustration.

The classical outbreak of amebic dysentery[4] in 1933 in a Chicago hotel was characterized by three successive peaks in incidence, a cyclic distribution caused by periodic contamination of the water supply. A similar cyclic distribution of injuries occurred among soldiers of an infantry division in France in 1944, when three successive and distinctive outbreaks of cold injury and trench foot[5] followed major military activities and increased exposure to cold, with the central and major event readily identified as a consequence of the Battle of the Bulge.

Other diseases are characterized by a non-fluctuating endemic prevalence of which tuberculosis[6] furnishes a good example, case rates for the United States during the years 1943–1947 adhering closely to a level of about 90 per 100,000 population. Certain classes of accidents conform to the same pattern,

FIGURE 2—Annual Seasonal Incidence: (a) Scarlet Fever,[3] Massachusetts, by Months, 1943–1947; (b) Motor Vehicle Accidents,[3] Massachusetts, by Months, 1943–1947

notably home accidents,[7] where year after year the death rates show little variation, sometimes a few more than 25 per 100,000 persons, and uncommonly a few less.



A well defined annual seasonal variation in frequency distribution is also a common characteristic of many communicable diseases. Scarlet fever in Massachusetts[3] regularly attains a maximum frequency in the winter months of January and February (Figure 2). An equally regular annual periodicity is shown by motor vehicle accidents[3] for the same state and for the same years illustrated, again a winter prevalence except that the peak develops somewhat earlier, in November and December.

The long-term trend in frequency distributions by time is another common method of evaluating the movements of disease, and a method that often serves importantly in determining the effectiveness of preventive measures that have been introduced. Injuries show typical trends (Figure 3), as definite as those of diseases, sometimes with frequency distributions maintained at a more or less fixed level, sometimes with a well defined tendency to move upward or downward. The downward trend in deaths from tuberculosis[8] in the United States during the present century is universally known, from close to 200 deaths per 100,000 population for the registration area of 1900 to a level consistently below 50 for the same region in the years since 1937. The frequency curve for deaths from accidents other than motor vehicle accidents[9] during the same period and for the same area was at a more or less constant level of about 85 per 100,000 during the first 10 years of the century; thereafter with a significant downward movement; with the past 15 years showing little variation although the level is now at about 50. Accidents as representative of the class of injuries evidently follow as distinctive movements in time as do diseases. It remains to determine whether the same biologic laws that govern occurrence and causation also act in respect to injuries.

ACCIDENTS AS AN ECOLOGIC PROBLEM

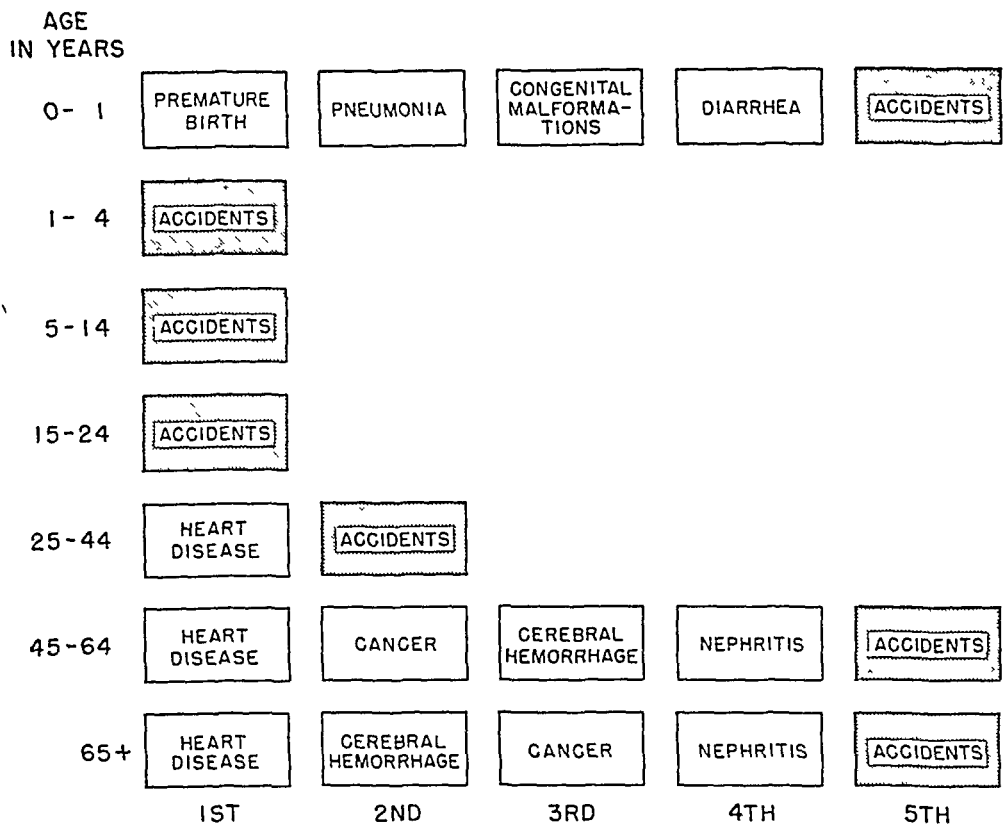
Irrespective of whether disease and injury be looked upon as affecting the individual, or as the mass effect exerted upon a community, causation is to be interpreted as something more than the agent directly involved, a germ in infectious disease or the loose board in a home accident. Rather it is a combination of forces from at least three sources, which are the host—and man is the host of principal interest—the agent itself, and the environment in which host and agent find themselves. Neither one nor

FIGURE 3—Long-Term Trend: (a) Deaths from Tuberculosis.[8] U. S. Registration Area of 1900, 1900–1946; (b) Deaths from Accidents, excluding Motor Vehicle,[9] U. S. Registration Area of 1900, 1900–1947

the other invariably exerts the principal effect, which provides the assumption that similar disease phenomena can arise from dissimilar causes.

An established and satisfactory equilibrium or adjustment between man and his environment leads to the situation called health. A significant disturbance of that equilibrium is the basis for disease or injury. The disturbance may occur either through principal action of the agent, because of a characteristic of the host, or as a function of environment, but most often through some combination of the three. These are the fundamental factors in causation. The mechanisms involved—how they interact to the eventual production of a pathologic condition, in pathogenesis of individual disease, or in the genesis of epidemics—is also a practical consideration, but the essential question is what are the basic causes of the disease or injury. This is true because remedy must be suited to the whole of cause, as it lies in host, agent, and environment. Can these broad biologic principles be fitted to an interpretation of injuries, as they have been to disease, whether communicable or non-communicable?

HOST FACTORS IN ACCIDENTS



Because the object or agent which directly gives rise to an accident is so evident—the faulty pavement, the scalding water, the unguarded poison—the common tendency to consider only that factor in a causative relation is readily understandable. An enveloping darkness, or rainy weather, or a crowded tortuous thoroughfare are also not so difficult to interpret as contributing to accidents. But the people who get hurt, they are only the poor victims; and yet when the question is examined, probably more causes of accidents lie within what we choose to call host factors, within people themselves, than in any other of the three parts of the triad which explain disease and injury. The host patterns of persons who suffer from accidents are of the same general order as those long recognized in many disease processes.

Age—Deaths from home accidents in the United States in 1945[7] were most frequent among the very old, past 65 years, and among the very young, aged 0 to 5 years, with the loss of life far less during the active periods of life, 5 to 65 years, when conceivably the opportunity for accidents is greater and the risk much enhanced. The distribution of deaths by age is so like that for deaths from pneumonia and influenza of the same region and for the same year, in the United States in 1945,[10] that the two are almost interchangeable. However, the whole significance of age as a host factor is not revealed by the absolute weight of accidents at various ages, for the situation is altered when the interpretation is in terms of relative importance. While the death rates for accidents are greatest at the extremes of life, the problem centers among children and young adults[10] when considered according to rank among causes of death (Figure 4).

Sex—Difference in attack rate by sex is another characteristic useful in distinguishing community diseases; from the outstanding predominance of males over females provided by tularemia and undulant fever, where other features than sex evidently enter, to the regular although less marked excess of males that characterizes mumps[3] and other diseases of childhood. The spread between death rates for males and females for accidents of all forms[9] is noteworthy, and particularly so when selected types of accidents are compared. Fatal accidental injury through falls is more than twofold greater for females than males at age 65 years or more, a reversal of the experience during childhood and for young adults.

Race—Racial differences in attack

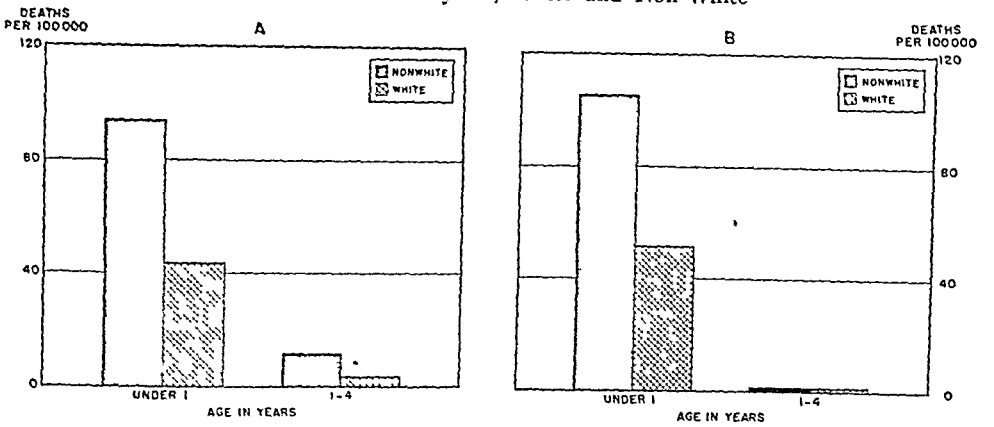


FIGURE 4—Principal Causes of Death,[10] by Age, United States, 1945

rates at earlier ages in a disease such as whooping cough[10] are well known, but they are no more striking than those noted for accidental suffocation[11] where the frequency is twice as great for colored children under 1 year as for white infants (Figure 5).

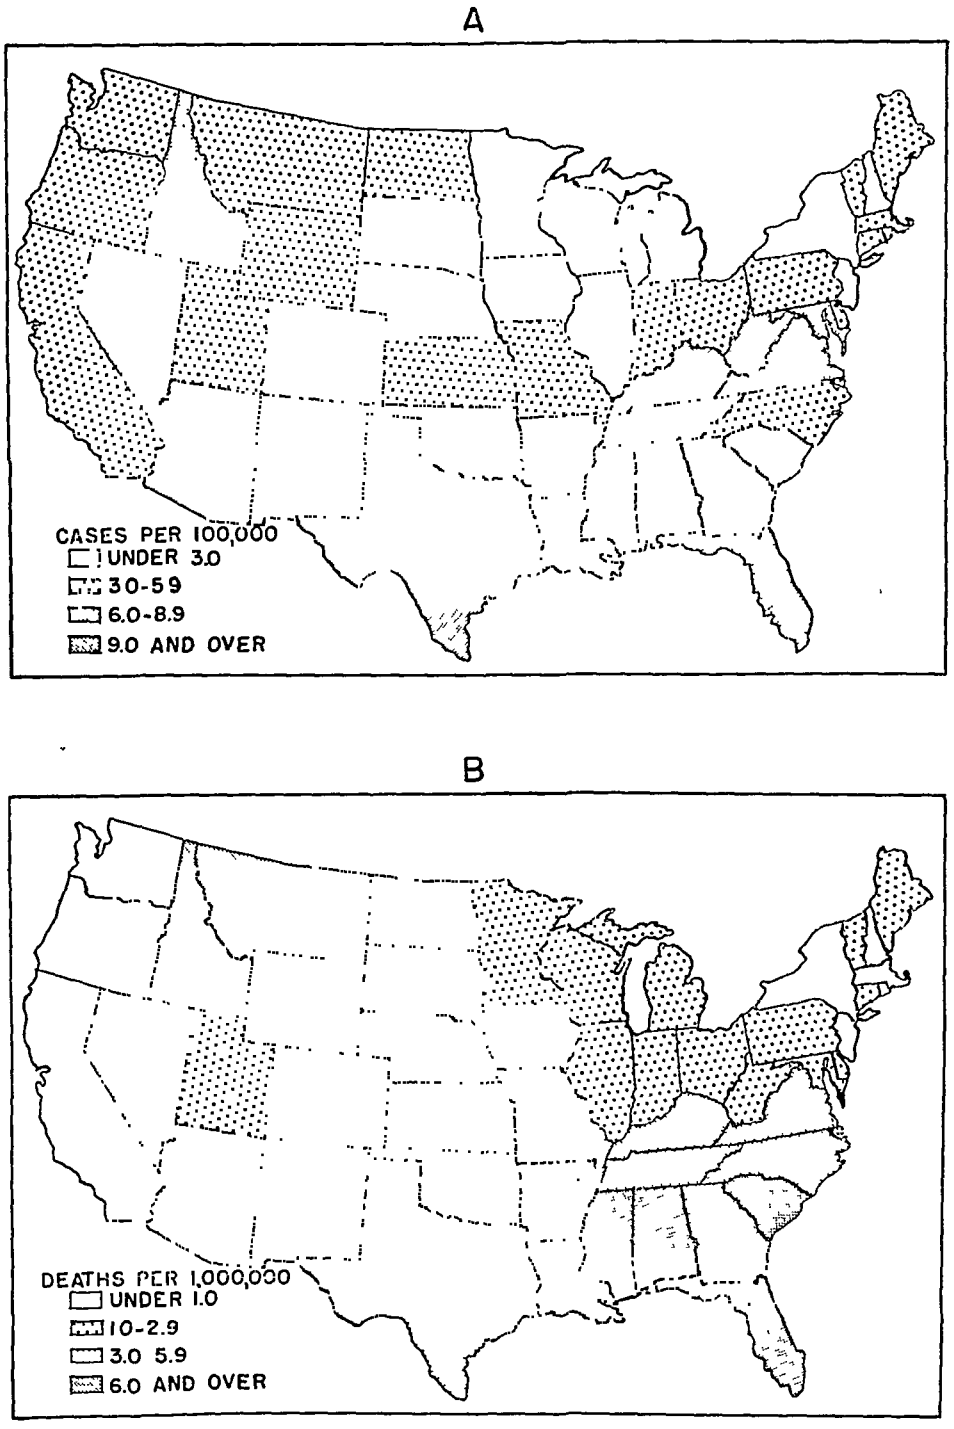
Genetic Inherent Susceptibility—The demonstrated differences in liability to accidents among populations separated according to the gross qualities of age, sex, and race are further confirmed by attention to any number of other features which enter into the constitution of the host as a whole, deficiencies in sight and hearing, and in mental stability to mention a few. Accident proneness is a host factor related to social attitudes and psychologic differences, and yet apparently is as inborn and fixed as any other inherited characteristic. The subsequent experience of motor car drivers who had no accidents in the first year of driving was compared by Farmer and Chambers[12] with those who had three or more. The accident prone drivers continued regularly to have more accidents during the next four years, a relation that held despite weather and other environmental conditions which introduced expected fluctuations in the frequency curve. Accident proneness is no unique function of motor accidents but enters into accidents of all types, although less well explored for such important groups of accidental injuries as those that occur in the home. The inherent differences among people in this attribute are as distinct as those underlying the excess incidence of acute upper respiratory infections[5] among white as compared with

FIGURE 5—Racial Distributions: (a) Deaths from Whooping Cough,[10] United States, 1945; (b) Deaths from Accidental Mechanical Suffocation[11] United States, 1939–1941; Children under 5 years, White and Non-White

colored troops, a phenomenon recorded in World War II, and in similar relation whether the endemic common cold or epidemic influenza prevailed.

AGENT

The agents concerned with injuries and with accidents, like those of disease, are variously of physical, chemical, and biologic nature. The importance of the several classes is greater in some types of accident than in others and the kind of agent within a class is potentially great. Information about the agents concerned in accidents is none too satisfying because of the common failure to distinguish mechanism from actual agent.



The causative factors in accidents have been seen to reside in agent, in the host, and in the environment. The mechanism of accident production is the process by which the three components interact to produce a result, the accident; it is not the cause of the accident. Kinds of mechanism serve to advantage in classifying accidents by type, with a particular event ascribed to cutting or piercing, to collision, or to crushing, and yet the agent in all three instances is a glass panelled door. Conversely, a fall may be related to such dissimilar agents as a faulty ladder, a playful pup, or a misplaced handbag.

The significance of agents in the problems of causation becomes more apparent when the kind and concentration are related to the same fundamental features of time-place-person relationship that is the basis of the epidemiologic method. This may be illustrated (Figure 6) by the geographical distribution of cases of typhoid fever[13] and of deaths from lightning,[14] with the dominant "reservoirs of infection" and factor of community dosage as evident for the one condition as for the other.

ENVIRONMENT

The limited perspective with which environment is commonly viewed is open to improvement by considering it as composed of three major elements, the physical, the biologic and the socio-economic, a concept elsewhere discussed in detail.[15] The physical environment has to do with matters of climate and weather, of season and topographical affairs, with soil and terrain, and the other physical features of the world where man lives. The biologic component of the environment can be taken to include the universe of living things that surrounds man, all else than man himself; while the socio-economic part of environment is that which comes into play through association of man with his fellow man. Environment so con-

FIGURE 6—Geographical Distribution: (a) Cases of Typhoid and Paratyphoid Fever,[13] United States, 1940–1944; (b) Deaths from Lightning,[14] United States, 1940–1944

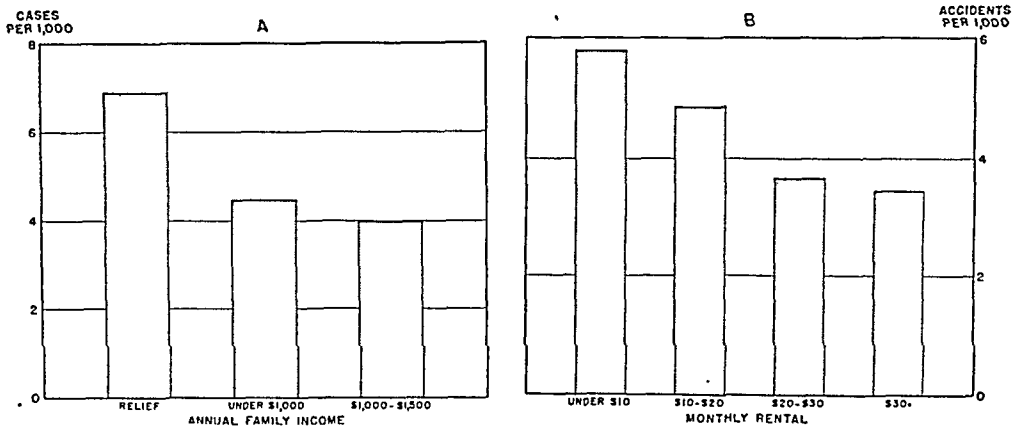
sidered exerts an influence on disease sometimes through direct action on host or on agent, and sometimes on the mechanisms which bring host and agent

together or determine their interaction. The results of environmental influences are to be measured by the character of the disease process that results, by the extent and nature of the frequency distributions that follow, and often by both. The three factors of environment are now considered as they act in determining distributions of accidents.

PHYSICAL ENVIRONMENT

The geographic differences in frequency of deaths from accidents of all forms are well recorded in the United States over many years; the highest rates are in the far West and in Florida, the lowest in the Middle Atlantic and New England areas.[7] The general pattern by no means holds for the various classes of accidents, notably home accidents, nor does the gross differentiation by states permit the individual community to judge its particular problem logically. This has been recognized to the extent that some cities determine the frequency of accidents by political subdivisions such as wards or census tracts, and states like Tennessee[7] and Kansas[21] have effected divisions by counties. Further division can be made according to classes of accidents, for example, those that occur in the home or in association with motor vehicles.

The contrasting frequency of diphtheria and scarlet fever in the cities of Sao Paulo and Santos in Brazil is a striking example of the effect of climate[16] on disease. The average annual mortality rates per 100,000 in Sao Paulo were for diphtheria 10.8, for scarlet fever 7.6; in Santos, diphtheria 3.1 and scarlet fever 0.3. The two cities only 49 miles apart are climatically wholly distinct since Sao Paulo high in the mountains has a temperate climate, while Santos is on the tropical sea coast. An equally striking effect of temperature is seen in the frequency of cold injury among American troops in France in World War II.[5] As temperatures dropped from November through January, the number of soldiers developing trench foot progressively increased.



A seasonal effect on injury and accident as striking as any that characterizes a communicable disease can be had by comparison of the distribution curves for cases of poliomyelitis[13] and accidental deaths from drowning[7] in the United States in 1945, the two curves being almost identical. This random choice illustrating a summer prevalence is easily duplicated, for instance by deaths associated with falls at all ages and suffocation of infants aged less than one year, which are typically winter diseases. The examples are sufficient to establish the principle that types of accidents have seasonal variations which can be as regularly recurring and as well marked as those for infectious or other disease processes.

The frequency of ascariasis in a rural area of West Virginia and in rural China is presented as an influence of soil and terrain on the frequency of infestation with an intestinal parasite. The rates for children under 10 years were respectively 58 per cent and 82 per cent. The introduction in West Virginia of the socio-economic factor of shoes being worn as age advances leads to comparative rates of 20 per cent and 63 per cent for those aged 40 years or more. Terrain can likewise act on motor accidents, as seen in a comparison of death rates in Rhode Island and in Arizona, where the regularly maintained ratio is 1:4 although assuredly analysis would show strong effects for socio-economic environment and from host factors, in addition to the character of the countryside.

BIOLOGIC ENVIRONMENT

The biologic factor of environment has a lesser significance in the causation of accidents, compared with the outstanding part it plays in such mass dis-

FIGURE 7—Influence of Socio-economic Environment; (a) Pneumonia,[18] Cases per 100,000, by Annual Family Income, National Health Survey, 1935–1936; (b) Home Accidents,[18] Cases per 100,000, by Monthly Rental, National Health Survey, 1935–1936

eases as malaria and rabies. That the principle holds, that environment in relation to accidents is also to be interpreted in terms of the three components already differentiated, is substantiated by a consideration of such events as the home accidents associated with pets, with poisoning through action of snakes and arthropods, and similar incidents related to the animate things that live with man.

SOCIO-ECONOMIC ENVIRONMENT

Whatever the kind or nature of mass disease or injury, the part exerted by the socio-economic environment is probably the most neglected of any epidemiologic influence, and accidents are not different in this respect from any other causes of damage. Only scattered information can be put together, that arising from the National Health Survey of 1935[17] being most instructive. The quality of housing (Figure 7) as judged by the amount of income or rental paid has been repeatedly demonstrated as an influence on the frequency of both communicable and non-communicable disease. It is not surprising that the same causative factors which act so strongly on the frequency distributions of pneumonia[18] are also a determining influence with accidents.[18]

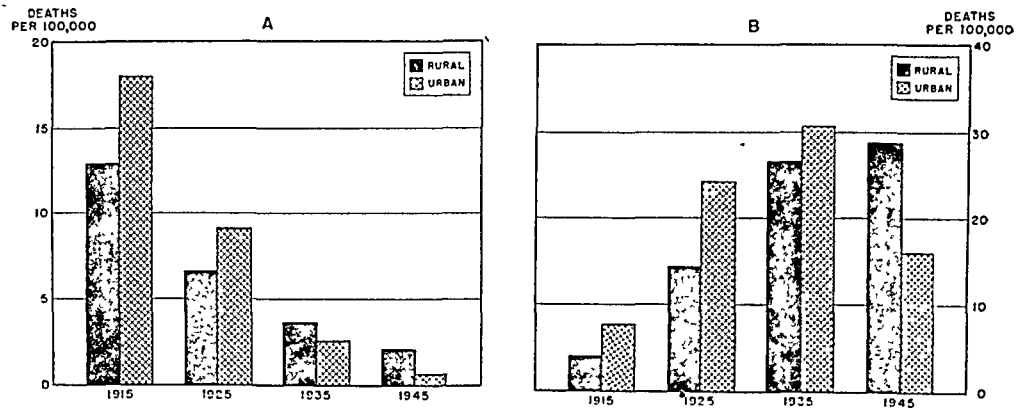
The demonstrated correlation between disease and occupation, as in tularemia[19] where hunters and housewives are the groups most affected, is in complete agreement with the differences noted for accident rates according to occupation.[7] Deaths per 100,000 for persons engaged in mining, quarrying, oil and gas wells were in 1947 about 170; for construction work and those in agriculture about 50.

The changing frequency in the incidence of the common communicable diseases among rural and urban populations is commonly advanced as a feature of modern disease behavior related to social and economic conditions. It is no more definite than the transition noted for motor accidents.[10] Deaths from this cause were dominantly a feature of urban populations 25 years ago, but the recent shift is of such extent that rural death rates now exceed those of urban areas.

THE EPIDEMIOLOGIC APPROACH TO ACCIDENTS

The idea that injuries as they affect groups of people could be profitably approached through epidemiologic methods grew out of a real and pressing experience in World War II. A type of cold injury, trench foot, involved

thousands of men, and was a major cause of disability and lost man power. The initial inclination was to look upon the cause as cold, which could neither be eliminated nor adequately controlled in an army operating under field conditions. If not cold, then the cause was deficiencies in clothing and equipment. It soon became apparent that other factors were of greater relative moment, the kind of military operations, the terrain through which troops operated, the management of troops, and an intangible host factor called foot discipline. Occupational components of a division were not uniformly affected, for commonly some 94 per cent of cases were among the 27 per cent of riflemen. Two units operating under similar conditions were disproportionately affected, and the explanation was sometimes related to host, sometimes to the agent, and sometimes was found within the environment. The problem of prevention resolved into a determination of the specific factors contributing to cold injury of a particular unit. From knowledge of those factors a specifically directed program of correction was evolved.



With a return to civilian interests, it seemed reasonable to suppose that accidents as a type of civilian injury could be approached in similar fashion and a study was made of home accidents. The broader presentation given here is advanced in the belief that the method is usefully applicable to accidents generally.

That accidents and disease, as they affect groups of people, so frequently show similar distributions is no reason to assume identical causes; indeed, the expectation is that they are different. The illustrations presented here were purposely drawn from a wide variety of accidents and diseases, to the end of demonstrating that both great classes of morbid conditions of man are governed by broad biologic laws; that in their action on groups of people they are the resultant of the total forces within a universe, of an ecologic entity. An observed behavior is no more a function of all kinds of accident than of all diseases, and conversely a single type of accident, like an individual disease, rarely manifests all the kinds of possible distributions.

Each of the three broad factors in causation has been considered individually to the end of demonstrating principle, but the illustrations themselves, and more particularly the concept of epidemiology as medical ecology, show this to be an over-simplification. All factors are intimately interwoven, each influenced by the other. For a given kind of accident the values are determined by subjecting adequate quantitative data to partial and multiple correlations in search for those conditions of actual importance in the particular situation. Too often the emphasis is on amassing facts with a failure to muster the power that likes in generalization, to develop information from principle or to collect data for a specific purpose and to meet a demonstrated need. A wide range of conditions commonly contributes to the prevalence of an injury. The success of a control program depends on sorting out from the larger volume those that are critically essential. These considerations make epidemiologic analysis a practical approach to an improved understanding of accidents and to a better prevention.

The start is through field investigation, individual case study of the patient, the family group, and the immediate surroundings in which they live. Neither disease nor injury in a community can be effectively prevented or controlled without knowledge of when and under what conditions cases are occurring. The method is fundamentally that so well developed for communicable and other diseases. The nature of the accident is determined, the result evalu-

FIGURE 8—Urban and Rural Distributions: (a) Deaths from Diphtheria,[10] per 100,000 population; (b) Deaths from Motor Vehicle Accidents,[10] per 100,000 population; United States, 1915–1945

ated in terms of death or recovery, of temporary disability or permanent defect. The causes are sought through direct investigation of the site of the accident, of the associated circumstances, and of the person who was injured. A principal difficulty is in unearthing the index case, in case finding, for the system of reporting so useful in the study of communicable disease and some few other conditions, is not available for accidents. Deaths from accidents are reported, but what is needed is something more than a knowledge of fatal accidents.

Death is far from being the sole health cost of accidents,[20] or for that matter of any mass health problem. Estimates suggest that for every death from a home accident, some 150 disabling accidents occur, a ratio that is greater than for any other of the accepted classes of traumatic injury. Patients admitted to hospitals serve as a lead to the group likely to suffer permanent defect from accidental injury, for presumably they are the more seriously injured. The kind of information basically essential to a comprehensive preventive program is that which relates to the bulk of lesser events, the accidents that result in temporary and often minor disability. This is to be obtained most surely through organized survey and special studies in selected areas. Much can be accomplished by incorporating the investigation of accidents into the ordinary activities of health departments where public health nurses and others include a consideration of accidents along with other activities which take them to the homes of people.

An analysis of collected data according to the pattern described is believed helpful in understanding the origin of accidents, since it provides a framework into which endless scattered observations can be fitted. It involves first a recognition of the agent involved, second a determination of the mechanism by which that agent comes into play, and thirdly a definition of cause in terms of combined effect originating from host, agent, and environment.

This is not a complicated but a rational and practical approach to the study of accidents. It is a scheme followed by several health authorities.[21] The National Safety Council[22] has made an analysis of home accidents according to this pattern. The investigation form used by the Kansas State Health Department provides a simple means for acquiring and recording necessary data. The method needs wider application if the problem in the individual community is to be adequately met, for it provides the intelligent and specific information upon which to build a program of prevention.

CONCLUSIONS

Specifically directed prevention based on an understanding of cause has long guided the attack on communicable and other diseases. The technical method is that of focal attack, a concentrated effort on recognized centers of infection and the causes that brought them into being.

The biologic principles that govern disease as a community problem are interpreted as holding equally well for injuries. A pattern for epidemiologic analysis is presented as a means for a better understanding of accidents, and thereby through improved measures of prevention, a lesser cost in death, defect, and disability.

Southern Branch A.P.H.A. To Meet in Dallas, April 14-16

The Southern Branch of the American Public Health Association will hold its 1949 meeting in Dallas, Tex., as announced, April 14–16 with headquarters in the Baker Hotel. John M. Whitney, M.D., formerly Health Officer of New Orleans, now with the American Red Cross, is President and George A. Denison, M.D., of Birmingham, Ala., is Secretary-Treasurer.

The preliminary program announces sessions that will include discussions of present trends in public health, medical research in public health, the tax dollar in public health, the importance of immediate personnel policy planning, water pollution, nursing for the future, rabies control, statistics in public health, dental caries, nutritional status of southern persons, early detection of cancer, public relations in health services, attracting young physicians into public health; together with special sessions on nutrition, nursing, laboratory, sanitary engineering, statistics and health education.

Bacillus subtilis, an Interfering Organism in the Enterococci Test

GRACE McCORMACK

U. S. Department of the Interior, Fish and Wildlife Service, Branch of Commercial Fisheries, College Park, Md.

IN testing the extent of fecal pollution of water and clam samples, the Enterococci Test of Winter and Sandholzer (*Technological Leaflet No. 2,* Fish and Wildlife Service, U. S. Department of the Interior, 1946) was run in parallel series with the coliform test. The inoculum was 10, 1, and 0.1 ml. of water or clam broth. All of the cultures which gave a positive or partially positive enterococci presumptive test were Gram stained. The results revealed that not all positive presumptive tests are caused by the presence of enterococci. Many times a Gram-positive, rod-shaped microörganism appears as a mixed culture with the enterococci, and sometimes, the color change is caused solely by this organism.

Since this organism appeared to belong to the genus *Lactobacillus,* the cultures were transferred directly to tomato juice agar slants, for further study. Later, differential tests showed that this organism was not a member of the genus *Lactobacillus.* Gram stains of old original cultures showed the presence of many spores, not apparent in a 24 hour culture.

Twenty-five cultures were given differential tests with twelve different sugars. The tests were found to agree in every case. Gelatin was hydrolyzed. Citrates were utilized. Acetylmethylcarbinol and nitrites were produced.

It is evident that the microörganism which interfered with the reliability of the enterococci presumptive test is *Bacillus subtilis.* A stock culture of this organism, as well as one obtained from the American Type Culture Collection, were run in conjunction with the differential tests on the isolated cultures. Similar results were obtained.

It is necessary to run the catalase test in order to differentiate between the enterococci and *B. subtilis.* If the growth of the Gram-positive rod-shaped organism is small, it is very difficult to detect a positive catalase test which is characteristic for *B. subtilis.* Of course, a differentiation can be made by Gram staining the cultures. All cultures were found resistant to large doses of penicillin.

Use of Auxiliary Personnel in Dental Care Programs*

R. M. WALLS, D.D.S., F.A.P.H.A.
Dental Consultant, Bethlehem School District, Bethlehem, Pa.

AT the annual meeting of the Committee on Administrative Practice of the American Public Health Association, held October 9, 1943, the Subcommittee on Medical Care was directed to draft a set of principles expressing the desirable content of a comprehensive program of medical care, the methods of its administration, and the part which public health agencies should take in its operation. The report eventually, by action of the Association on October 4, 1944, became an official statement of the A.P.H.A.[1]

The study was considered but one sector of a comprehensive national health program, namely, medical care. The report states, under recommendation VI "Training and Distribution of Service, Personnel," b, that "The plan should provide for the study of more effective use of auxiliary personnel (such as dental hygienists, nursing aides, and technicians) and should furnish assistance for their training and utilization."

The study of the more effective use of auxiliary personnel for the dental profession was assigned to Nathan Sinai, Edwin F. Daily, and R. M. Walls. This study has not been completed and is not ready to be presented to the committee, hence the material offered here represents the views of the author alone.

According to O'Rourke[2] there are five or six trained auxiliary workers for each physician and approximately two-thirds of such aid for each dentist. At first there was much opposition to the formal training and the registration of nurses. But while there was one nurse to each physician in 1920, in 1940 there were two to each physician. This is but one example of the evolution of auxiliary groups in the medical field. The physician has been wise in delegating so many services to ancillary aides —from the construction and fitting of artificial eyes and limbs to the multitude of laboratory technics.

The dental profession has been very reluctant and slow to accept the services of auxiliary personnel. The "chair assistant" has assisted the dentist for a century and, according to Klein, those who avail themselves of such well trained aides increase their service to the community 25 to 50 per cent, yet today less than one-half of the profession have such assistants. Dentists have been required to spend most of their time meeting the demands for fillings and restorative appliances for adults. Some items have been delegated to specialists, but, as compared with a solution of the whole problem, this delegation has not been significant.

Many dentists or groups of dentists avail themselves of the services of prosthetic laboratory technicians, either working under close supervision or off the premises under no direct professional supervision. This type of auxiliary worker undoubtedly saves the dentist many hours in actual labor, but little

* Presented before a Joint Session of the Dental Health and Medical Care Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

of this time helps to produce more chair hours because it is rare that a dentist who can otherwise fill his chair-time hours will spend such time in his prosthetic laboratory, and so such work is done during the evening. It can truthfully be said that the use of the laboratory technician as an auxiliary worker does not make more chair-time available so that more patients may be served by the dentists.

The only auxiliary operator in the dental field that has legal status is the hygienist, and the tumult that raged within the profession at the time of the conception of this new idea may still be heard each time that a state attempts to amend its laws to permit the licensing of hygienists. In the first decade of the 20th century, Dr. D. D. Smith of Philadelphia, propounded and demonstrated some of the potentialities of dentistry as a health service. Dr. Alfred C. Fones, of Bridgeport, Conn., was so impressed with the work of Dr. Smith that he conceived the idea that the subject of oral health was of sufficient importance to warrant the training of individuals who would devote their chief energies to dental prophylaxis and dissemination of information to the public, through the schools, in regard to the value of a clean and properly functioning oral cavity to personal health. As a result of Dr. Fones's indefatigable efforts, a school for dental hygienists, with a faculty which has probably not been equalled since, was established in Bridgeport in 1913. Since that time the dental hygienist has been licensed by 38 states, and almost without exception has become recognized as an important ancillary to modern dental health service, yet they are found in only 4 per cent of dental offices. This auxiliary operator, without proving a threat to the established form of dental practice, has so conclusively demonstrated her worth to both institutional service and private practice that she has become as essential to modern dentistry as the registered nurse is to modern medicine. In private practice the great majority of her patients are adults; it would be of great significance if the time that is saved by her employer were spent in rendering service to children.

How do our educational facilities measure up to the problem of supplying sufficient graduates in dental surgery to meet the present-day need?

It is interesting to note that in 1900 there were 57 dental schools, in 1921 45 dental schools, and in 1933 but 39. At the present time there are 41 schools, only two of which offer dental training on a large scale to the Negro. Horner [3] states that many factors enter into the fixing of the numbers of students in dental schools and the number that are graduated, such as wars, depressions, and changing entrance requirements. The highest enrollment since 1925 was 9,014 in 1943, and the highest number of graduates since 1928, 2,470 in 1944. This increase was due to the accelerated plan of instruction operating during the war. The lowest enrollment since 1925 was 7,160 in 1933, the result of the depression in 1929. The lowest number of graduates since 1930 was 1,568 in 1941. This decrease was in part due to the effects of the depression, and in part to the increased requirements that went into effect in 1937.

If we accept Horner's figures, the number of dentists in this country in 1941 was 75,685 or 1 to 1,740 of population; in 1945—77,188, or 1 to 1,801 of population; and he estimates for 1950—76,632 or, 1 to 1,933 of population.

These data of Horner's [3] show an estimated loss of dentists, steadily, after the year 1947. Even with the creation of three new dental schools, which should provide the graduation of 2,500 dentists per year, and if from 1950 to 1960 we should have the expected increase in population of 6 per cent, we would have 82,500 dentists in 1960 and a popula-

tion per dentist of over 2,000. Thus it would appear that our population per dentist for the 3 decades from 1930 to 1960 will show a progressive increase and that the provision for dental care will be less in 1960 than it was in 1930.

If the many programs of health education in the past 3 decades have had the desired effect, there will be greater demands for dental services in general. Improved methods of transportation are making dentistry available to many in the rural areas. Organized groups are including dental services in their health programs. The new Army program will further disjoin the dentist: population ratio.

Says Morrey,[4]

> Since the number of graduates from dental schools is influenced by many things which upset the increase in the number that should be expected to take care of normal growth of the population and since it requires so many years to reëstablish this normal output, all plans for the expansion of dental service to the population are put in jeopardy, it would seem to me that some other plan for increasing the man-power is in order.
>
> There is no disputing the fact that, during the past fifteen years, the supply of dentists has not kept abreast of the public appreciation and demand for service; and that as a result, in the United States, dentistry is seriously undermanned. Any dental program, whether inaugurated on a national, state, or local level, must take that fact into serious consideration. Judging from existing figures and by the upward trend in public appreciation of dental service, it seems safe to predict that the dental profession will be barely able to meet current dental demands and that, under present methods of practice, the profession will be exceedingly over-taxed to supply anticipated future demands.

Again quoting from Morrey[5]:

> Until that day dawns when therapeutic measures can be employed to prevent dental caries, the dental profession should bend its every effort and the efforts of its auxiliary forces toward controlling caries by the most practical method known at the present time, namely, dental operative procedures for children. This is not a new formula, on the contrary, it is one that has been advocated for many years. Unfortunately, it has never been wholeheartedly accepted by the public, and it has been accepted only in principle, but not in fact, by many members of the dental profession.

Klein[6] has made a rather exhaustive study of the needs of the population and has estimated the number of chair-hours that would be required to take care of the accumulated needs and the yearly incidence of decay. Time will permit but one quotation: "The yearly crop of dental need in the whole American population requires for its service probably at least double the present volume of dentists, that is, instead of 65,000 dentists, at least 130,000 are required, just for yearly maintenance." It is interesting to note that in the 107 years since the first dental graduates were sent forth there have been but 126,500 following in their footsteps.

Unfortunately the child suffers most from the lack of man power, pointed out so convincingly by Klein. There are but two or three hundred dentists in this country who devote their entire time to dentistry for children, while the general practioner seems largely indifferent to the needs of the child. Children are apt to be difficult patients, making it hard to render good service and, in the hands of most operators, limiting the types of materials that may be used for fillings. Rarely are inlays indicated or possible; rarely are crowns and bridges inserted. Dentistry for children is not made available in many offices because it brings comparatively small financial returns. Yet children should receive more dental service, beginning at a very early age and on a constantly continuing basis.

Consider just one of the ills that beset the child who does not receive dental care: the early loss of deciduous teeth and of the six year molar—resulting in the drifting of teeth—is one of the greatest causes of malocclusion of the jaws. It has been estimated that 60 per cent of children today have malocclusions that should be treated by the orthodon-

tist. The services of the orthodontists are necessarily costly, and there are far too few to serve the need. Such services are but rarely available to those in the low income group; very few clinics offer such services to the indigent.

Bauer[7] states that the fact that the child receives secondary consideration was impressed forcibly upon the laity and the profession in the reports of Selective Service. He feels that the lack of financial returns, poor patient management, the lack of preparation provided by many schools, and the subordinate place of pediodontics in state board examinations are responsible for this lack of service.

Salzmann[8] observes that it requires a general depression such as was experienced in the early and middle 30's to make the profession turn toward meeting the needs of children, and that during the war and since then, pediodontics has reached a very low ebb. The American Dental Association and various state and local dental societies, recognizing this trend, made appeals on professional as well as patriotic grounds that children be given priority appointments, but in spite of a high per cent of pledges by the profession, in actual practice it was found that children were not being favored. Salzmann goes on to state "that between the unwillingness of the private dentist to meet his responsibility to children and the growing demand upon the part of interested lay groups, it may well be that the provision of dental care for the children will be taken out of the hands of the profession altogether. Already there is talk of developing auxiliary workers to care for the children."[9, 10]

Jeserich[11] states it this way:

> The present regime of practice demands a heavy concentration of effort and thinking on technical procedures, based vaguely on a rather confused background of biologic principles with a gradually fading consciousness of their significance and as a result a waning effort to correlate them with clinical practice. More hands especially trained for technical procedures under the direction and supervision of the licensed dentist . . . with a practice regime permitting the use of this concept to guide his and the hands of others, would seem to be desirable from the points of view of both quantitative and qualitative service considerations. Part of medicine's greater appeal when compared with dentistry is due to the fact that it affords an opportunity to use the mind without so much emphasis on technics. Dentistry's thinking is too fettered to technics by the nature of its present system of practice. In medicine, nurses, technicians, interns, and other aides make it possible for one mind to direct and guide several hands and minds trained to be auxiliary aides.
>
> The dental profession seems to fear that something will be taken away from it whenever the creation of any group of auxiliary aides is discussed. As long as these aides are under the immediate supervision of properly trained ethical practitioners, and have had adequate training for their limited function, such fears do not seem logical and would appear unwarranted. It would be more logical to presume that something was being given to the profession rather than taken away, both from the objective of quality and quantity of service and from the point of view of economic considerations favorable to the profession as well as to the people served. The violations of auxiliary aides would be dependent entirely upon the ethics of the licensed practitioner, and in the last analysis the profession of dentistry. There would have to be a deliberate breach of ethics or law by the profession to have violations. Are we afraid of ourselves or the auxiliary aides?

I would like to quote Elam[12]:

> It is my considered opinion that the time has come when the dental profession must broaden its auxiliary services if it expects to meet the increasing demands upon it. At the same time it must protect its present standards of dental education and exert firm control over all phases of dental service. . . . The fact is, as I see it, the dentist without help cannot possibly supply the demands for all dental services. The demands are increasing daily and unless the demands are met by the profession, other agencies will seek to supply them. This can be done in many ways as has been attempted in other countries. The only solution for the profession, to meet its obligation to the public, is to accept, train, and control all the help that it needs.

Since the number of new graduates entering practice each year is not to any

great extent exceeding the number of practitioners who retire or die annually, it is obvious that making dental service more readily available to the public cannot be brought about for many years by merely adding to the total of practitioners in the usual way. The previously mentioned committee of the A.P.H.A. is well aware of this fact, and after reviewing the present use of auxiliary personnel by the dental profession—the hygienist, the chair assistant, the laboratory technician, as well as the use of multiple operating units—finds that these present practices fall far short of producing the man power hours required to meet the present demands for dental service and that the development of a new type of auxiliary worker should be considered, if more extensive public health programs in the dental field are to be made possible.

A study of the system in use in New Zealand has been made and brings to light the following: The government in 1919, reviewing the health of its armed forces during World War I, determined to do something about the dental health of its children, and instituted the New Zealand School Dental Service. In 1920 Col. T. A. Hunter, C.B.E., Director of the Army Dental Service during the war, was appointed Chief Dental Officer of this post-war service.

Colonel Hunter's proposals were considered revolutionary but eventually the New Zealand Dental Association gave its formal approval of his proposals and the first draft of young women to undergo training as dental nurses was appointed in 1921.

This service, created by the government, organized and controlled by the Director of the Dental Division of the Department of Health, was organized in six units, each of which is controlled by a senior dental officer who is directly responsible to the director. These officers are the Principal of the Dominion Training School for Dental Nurses, and the Senior Dental Officers in charge of the five dental districts into which the Dominion is organized.

Graduate school dental nurses are officers of the Department of Health, but they are "attached for special duty" to the staff of the school at which their clinic is situated. While they come under the general jurisdiction of the Headmaster, their actual controlling officer is the Senior Dental Officer who is assisted by a staff of inspectors and assistants.

The school dental nurse receives her training in a special school at Wellington. The applicant must be a young woman with high physical fitness, good personality, between the ages of 17 and 25 years. She must have passed, as a minimum requirement, the university entrance examination or school certificate examination. She must agree to serve for not less than five years, including the two years training period. The cost of the training is borne by the government.

The curriculum is well planned to provide the student with the ability, among other things, to fill and extract deciduous and permanent teeth. The senior Dental Officer or his aides are consulted in regard to any patients who present conditions which appear to require special treatment. Health education is stressed, so that the patients may be instructed in the principles of oral hygiene and the preservation of the teeth.

There is no means test. All children are eligible, irrespective of the social or financial position of their parents. Attending school is a prerequisite to obtaining dental treatment, except in the case of preschool children and adolescents. It is necessary to enroll while in the primer classes, that is, not later than the second year of attending school but enrollment during preschool age is preferred and encouraged. It is interesting to note that eligibility for the ex-

tended service that embraces the adolescent group is contingent upon a person having undergone regular treatment up to within three months of the time of application, either at a school dental clinic or at the hands of a private dental practioner.

Every patient is required to undertake: (a) to attend for treatment or examination at such times as may be required; (b) to apply for treatment as soon as he becomes aware that treatment is needed; (c) to apply for examination at an interval of six months from his completion (the responsibility for this is placed on the system, but the patient should draw attention to any omission to call him up); (d) faithfully to carry out such instructions as are given in regard to oral hygiene and dental health.

If a patient should fail to report within twelve months of his previous completion, his name may be removed from the roll. He may be reënrolled if he has his dental condition restored to a satisfactory standard at his own expense.

The school dental nurse supplies the service for the child until he reaches the age of 13. Not more than 500 children may be assigned to one nurse. The adolescent group, recently included in the program, is served by dentists.

The annual report for 1946–1947 shows that for the year ending March 31, 1947, there have been established 456 treatment centers; the staff numbered 679 including 206 student dental nurses. There were 423 school dental nurses in the field. There were 226,798 children under treatment; 2,313 schools were embraced in the treatment areas. From the report I note a ratio of 6.3 extractions to every 100 fillings, which is quite a contrast to 114.5 extractions per 100 fillings in the first year of the program. The cost of the service per child was approximately £1 per annum. The costs include salaries, maintenance of hostels for housing the student nurses, and buildings. The school dental clinics in the field are built by the Educational Department and are not included in the cost figures. The cost of training a dental nurse in the last yearly report was given as £600 for the two years. Against this figure is assessed the value of the clinical services which are rendered during the second year, of £200, making the net cost of educating the dental nurse £400. I have long been of the opinion that this program which has been in operation in New Zealand for 27 years, if introduced into this country would in time solve the problems that have been stated by Morrey, Salzmann, Elam, Klein, Jeserich, Millberry, Clawson, McCall, and others.

I have discussed with the deans of several dental schools the possibility of producing a course comparable to the one given in New Zealand at the training center for school dental nurses in Wellington. Without exception these men stated that it would be possible to provide a similar or better course of instruction at their institutions.

Clawson[13] said recently that he and his colleagues at Meharry have given considerable thought to a plan which is based on their willingness and ability to offer a curriculum from which all subjects not essential for dentistry for children would be eliminated and only those subjects absolutely essential to good children's dentistry would be retained, in a two years course. I must refer you for further consideration of the rather elaborate plan to Clawson's complete statement, but let me quote briefly: "We would give it a trial tomorrow if I could find one state board that would give a licensing examination to the product of the course."

I have presented the picture of the present lack of dental personnel and the rather dubious outlook for the reduction in the future of the dentist; population ratio. I have not included

in this presentation an estimate of what proportional changes may result as the "draft" program gets underway, because at this time the picture is not clear.

I have very briefly outlined the need; it is so very well known to all of us. I have quoted various men, prominent in the dental health and educational field, who believe that an extension of the type and use of auxiliary personnel by the dental profession is indicated. I have given a concise statement of the system that has been in vogue in New Zealand for 27 years. I have quoted a plan that has been projected by a well known dental educator, who has had vast experience in dental education at home and abroad.

I am not unmindful of the strides that have been and are being made by scientists in their determination to discover the cause of dental decay and to apply their knowledge. The men who are outstanding in this field do not anticipate more than a 40 per cent decrease in the dental caries rate. Presupposing that, as a result of a general application of new knowledges, the adolescent enters adulthood with better teeth and more of them, and the life expectancy continues to be pressed upward, then there will be more of the diseases of the oral tissues that come with age to be treated. Naturally the field of the dentist would be extended with this new demand and the children who would require service would still not find it available.

There is considerable difference between the need for services and the demand by the population. But I cannot agree with a statement made recently that the demand rather than the need for dental services should be the guiding principles in increasing the number of dentists and auxiliary personnel.[14] I believe that dental services for children should be made readily available to every child.

I have long been of the opinion that a healthy mouth should be a prerequisite for enrollment in school and a requisite for the continuance in school. All existing obstacles that deprive children in the low income families or children on farms or in other sparcely settled areas, or Negro children, of dental services, would be removed if the state departments of health would make this new type of periodontist available to the schools. Hand in hand with education should go a healthy mouth.

In the opinion of the writer, which is shared by many others, a research project should be undertaken on this continent, in the United States preferably, so that the utilization of specially trained auxiliary personnel may be observed and evaluated by the profession. The personnel could receive a carefully worked out course of instruction, over a period of two years, at a recognized institution. Authorities in the field of pediodontics, dental education, and public health would advise and assist in the planning of the research project and the evaluation of results. It is to be hoped that some state will show a willingness to suspend its licensing law and be willing to sponsor the study. I believe funds could be made available.

Millberry, in October, 1938, at a joint session of the Child Hygiene and Public Health Education Sections of this Association presented a paper entitled "Possibilities and Means of Improving Dental Conditions in the United States." He said, among other things, "Does it not seem possible to you that we should be able to train persons to do these simple operations for children in two years time?"

When Dean Millberry's paper was published in the *Journal*,[15] the following was a part of the editorial that appeared in the same issue:

> There can be no doubt that the cost of dental treatment is high and that the funds for providing it on a community basis are all too small. Any relief, such as offered by Millberry, will seem welcome to public health

administrators, most of whom have little knowledge of the technical problems involved. Over against this group will be the mass of dentists who will probably prejudge this proposal on its departure from the *status quo* without inquiry into its possibilities. Without taking a stand for or against the Millberry plan, it at least seems proper to suggest its consideration by a group of dentists thoroughly familiar with the problems involved in giving dental care to American children. A critical evaluation of the New Zealand method seems desirable also, particularly with regard to its applicability to North America.

I am glad to report that now, after the passing of a decade since the appearance of the editorial quoted above, a committee of this association is actively engaged in studying this whole problem of securing more dental service for children and is planning steps to secure an experimental study of the use of the auxiliary operator with a two year course of education. These plans will require the support of all who are interested in medical care programs and particularly of those who wish to find a practical solution to the problem of providing adequate dental services for children.

THE HEALTH EDUCATOR'S BOOKSHELF

OUR spring issue, a year ago, carried a stimulating Review Article on the Health Officer's Bookshelf. The health officer is, of course, the star of our show, but he is not the only one who must read books. There are a dozen other kinds of specialists on his staff, who need a dozen kinds of highly specialized knowledges. How can they get those knowledges and keep them unless they read the classics in our field—and the latest books as well?

This train of thought led the collective Editorial mind to the thought of expanding the Baedeker of Health which Dr. Huntington Williams began to explore so fruitfully last year. And the Health Educator seemed a logical next step. He (or more often she) must know something about everything in the entire field of health. The old saw tells us that the cultured man should know something about everything—but also everything about something. The Health Educator needs a wide vision of the whole field; but he must have also a deep and solid grasp of his own specialty, which is the imparting of knowledge and—in still greater degree—that impulsion of the spirit which creates the desire to use the knowledge gained. This is no easy task; and it is no surprise to find that while Dr. Williams recommended 79 books to the Health Officer, Dr. George Rosen—in the admirable review with which this JOURNAL opens—lists 118 volumes for the Health Educator. No wonder, this gifted type of specialist coördinates and integrates and educates and animates.

If our readers find the Bookshelves profitable, perhaps the other eleven sections may have their turn in the years to come.

HOUSING AND THE HEALTH OFFICER

THE general program of our Association Committee on the Hygiene of Housing was reviewed in the columns of this JOURNAL two years ago.[1] This committee was established in 1937 as the corresponding organ of the Housing Commission of the League of Nations for this continent. In 1938, it published its first report on the *Basic Principles of Healthful Housing*[2]; and, in 1941, a volume

on *Housing for Health* presented the results of a special conference called by the Milbank Memorial Fund.[3] During the past decade, the committee has developed—and has very recently completed—a technique for the realistic appraisal of housing quality.[4] This procedure makes it possible for the average sanitary inspector, after a few weeks of training, to evaluate the quality of the home and its environment with reproducible accuracy and to assign to each dwelling a penalty score expressing its significant health hazards in quantitative terms. The appraisal method, as M. A. Pond points out in this issue of the JOURNAL, contains 12 clearly defined "Basic Deficiencies" on any one of which the health officer can base legal proceedings. Even more important, however, is the fact that plotting the total penalty score (based on sampling surveys) on a city map gives a realistic picture of the character of individual blocks and larger areas which furnishes the soundest basis for future planning and for the adaptation of correctional measures or redevelopment to a given locality. Through the use of this procedure, the health officer can really "know his city" accurately. The gradual replacement of sporadic action following haphazard complaints by a comprehensive planned program will work a revolution in housing control. This revolution has already taken place in many American cities, as pointed out by Emil Tiboni on a preceding page of this JOURNAL. Such communities as Battle Creek, Mich., Brookline, Mass., Los Angeles, Calif., Milwaukee, Wis., New Haven, Conn., Panama City, C. Z., Philadelphia, Pa., Portland, Me., St. Louis, Mo., and Washington, D. C., have employed the appraisal method with significant results.

Sponsorship for this appraisal procedure has now been taken over by the U. S. Public Health Service, which is in position to offer counsel to any health officer who desires to employ it and to provide training facilities for the sanitarians who are to carry out the work. We confidently look forward to the time when all alert city and state health departments will include systematic housing evaluation in their program, as they include restaurant sanitation and milk control today.

During the past two years, the Committee on the Hygiene of Housing has been seriously handicapped by limitation of financial support and loss of some of the key members of its staff. The Milbank Memorial Fund has, however, recognized the vital nature of the problems involved and continued its loyal support. The staff has been reorganized and committee members are ready to devote liberally of their own time to work along two major lines.

The committee has planned, first of all, to complement its completed work on the definition of substandard housing by the preparation of a series of reports on the principles which should govern the construction of the healthful housing for which we hope in the future. The first volume, on *Planning the Neighborhood*[5] has already been published and is discussed by F. J. Adams in his contribution to our Boston Symposium. The committee is now at work on two subsequent volumes on "Planning the Home for Occupancy" and on "Construction and Equipment of the Home." It hopes to complete the report on "Planning the Home" within the present year. Standards for this purpose are most urgently needed, since not only speculative builders but government agencies are today advocating homes so narrowly constricted in space as to constitute a serious threat to health and amenity. Space is one of the most valuable things which the home builder has to sell; and in ten or twenty years we may be seriously embarrassed in dealing with "the slums of 1948 and 1949."

A second major project of the committee is the formulation of a report on the substantive content of a model housing code, under the leadership of E. R. Krumbiegel. The problems of building codes to govern new construction are also serious; and the committee is convinced that reform in this area must be effected by substituting broad performance standards for the minute structural provisions now in force, which are out-of-date a few months after such a code is adopted. The housing code for occupied dwellings, has, however, been the major concern of the committee. Such a code, in its judgment, should be enforced primarily by the health department as the one agency which possesses the necessary technical knowledge and has a force of inspectors constantly visiting the homes of the community. It is hoped that the report of the committee on this subject will give the health officer a model on which can be based a sound section on housing for his local sanitary code.

We believe that the program of the Committee on the Hygiene of Housing illustrates a significant trend in the whole field of sanitation, toward the goal of positive promotion of health and not merely the negative prevention of disease. The water supply engineer is interested in addition of fluorine as well as in elimination of typhoid germs; the industrial engineer in thermal air-conditioning, as well as in control of lead fumes. As Catherine Bauer has said in her contribution to the Boston Symposium, "Sanitary measures were undertaken to curb the fearful epidemics of filth-bred disease. Then gradually it became clear that not only the absence of dirt but the presence of sun, air, and adequate space are essential to the prevention of disease. And finally the whole emphasis changed from a remedial approach to more positive and constructive goals."

FACING THE FACTS OF LIFE

THE Administration Bill, "to provide a national health insurance and public health program" (S 5 and H R 783) has been introduced in Congress. Its provisions—and its ultimate fate—will be of keen interest to all of us during the coming months.

Title I (a general Declaration of Purpose) need not concern us, since it is merely a statement of broad principles, to which almost everyone must agree. Title III, which deals with Development and Expansion of Health Services, provides for a continuation of federal grants such as the U. S. Public Health Service and the Children's Bureau have administered in the past. It is vitally important and some of its provisions may require consideration; but, in the main, it does not involve controversial issues.

Title II on Prepaid Personal Health Service Benefits, on the other hand, will be the central issue in a real battle. It creates a national system of health insurance covering employed (including self-employed) persons with certain family dependents of the insured. It is proposed that the plan be financed by a contribu-

tion equal to 3 per cent of all wages or net incomes up to $3,600 a year, with additional allocations from general tax funds. This measure obviously involves profound modification of our past social policy with respect to medical care. Its details will call for most careful analysis. We must consider whether the "tooling-up period" before the program would come into operation (in 1952) is adequate. We must be certain that the decentralization of the program to the state and local levels is as complete as appears at first glance. How will local areas be delimited and administered? What local advisory committees should be provided for representation of the professions and the public? How should a local medical care program be related to the jurisdictions of local health departments? Such details of administration and operation will require the most careful scrutiny, to avoid complications which have occurred in the introduction of the present British program. We must decide whether—and what—upper limits of income might be set for those receiving service. We must consider in what order of sequence particular services (hospital, office visits, home care, nursing, dentistry, etc.) should be provided for the insured. This last point is left for future administrative decision in the present bill; but it will vitally affect all aspects of the program. Estimates of cost and details of financing will require careful scrutiny. In these highly technical matters, we must rely on the advice of competent experts in this field. There are probably not more than twenty such experts in the United States (of whom the Editor of this *Journal* is not one); but ultimate responsibility must rest on all of us—after hearing the experts and considering their findings with open-minded reasonableness.

It is most important that we—in the public health profession—should consider this measure with a sense of special responsibility, since we do have some expert knowledge of the problems involved and since the administrative conduct of many aspects of the program may be in our hands. It is basically important that we, at least, shall view the problem honestly and on factual grounds and not be led astray by propaganda based on false emotional appeals.

The basic need for some method of making the beneficent results of American medicine available to families in the low-income and moderate-income groups (the great middle class of our population) has been amply demonstrated since the Committee on the Costs of Medical Care made its first study 15 years ago. It has, again and again, been shown that the less fortunate groups, in spite of our clinics and hospitals, receive less than half the medical care they need. The existence of the problem cannot be challenged. How can it be solved?

There are several possible solutions which have been suggested. The first of these is State Medicine, the provision of medical care to all citizens by public hospitals and by physicians and other professional personnel employed by the State, as we now provide education by State-employed teachers. This is the program of the Soviet Union; but it has no appreciable supporters—as applied on a wholesale scale to medicine—in the United States or Canada.

A second plan, now backed by a vigorous and vocal group in the United States, is extension of voluntary insurance (of the Blue Cross and Blue Shield Types), supplemented at the bottom of the scale by public medical care for the recipients of public assistance. This is a tempting program; and it operates with effectiveness for a certain relatively high income group. There are at present probably 3 million (certainly not more than 5 million) persons in the whole country covered by plans of voluntary insurance with fairly comprehensive scope. All others now classed as "voluntarily insured" are covered only for very limited

services. Both logic and experience indicate that such a program does not—and cannot—reach the large middle group of the population.

Families with an income above a certain level can meet even the emergency costs of illness when they arrive because they have an ample cushion of reserves on which they can draw in an emergency; these families get good medical care today, with no outside assistance. They constitute, however, only a small proportion of the population.

A second group of families have an income sufficient to meet the average cost of medical care but not enough to meet the emergency costs of illness as they arise. This is the group which benefits by voluntary insurance.

A third group of families—and a very large one—have incomes which are not sufficient to lay aside enough each year to cover even the average cost of medical care. This group cannot by any possibility share the benefits of voluntary insurance plans because they cannot afford the dues. It is this major group which a system of social insurance, financed by contribution from both the beneficiaries and their employers, is designed to serve.

If our rejection of State Medicine is sound (as it certainly is); and if Voluntary Insurance cannot possibly serve those unable to "volunteer" the money which they do not possess; there would seem to be three possible courses to pursue.

We can decide to do nothing about the matter except to develop Voluntary Insurance for the relatively high income groups; but it is doubtful if this policy can be indefinitely pursued in a democratic society, to which we have been preaching that—in the words of the WHO Constitution—"The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition."

Or, we can accept the broad principle of social insurance, supported jointly by both employer and employee, and strive to perfect the details of a program of this sort so as to make it most effective and most economical, and so that it will be conducive to the highest possible standards of quality of medical care.

Or, perhaps, someone can devise some better way of meeting the basic problem. An adequate and universally acceptable plan would be a major boon to the United States and Canada, both of which nations are facing the issue in the immediate future.

But the problem cannot be solved by an ostrich policy of sticking our heads in the sand. It cannot be solved by denying its existence. It cannot be solved by asking families to join in support of voluntary insurance and pay out money which they do not possess.

It can only be solved by facing the basic economic realities of life.

THE PROBLEM OF HEART DISEASE

PRIORITY decisions in public health policy must be based on a balance between the magnitude of a given menace to health and the efficacy of available methods of meeting that menace. If a certain disease kills ten people a year in the community and we know how to control it, that disease takes priority over another which kills a hundred people but is not susceptible to demonstrated methods of prevention. From the standpoint of magnitude, diseases of the heart and blood vessels clearly constitute our Number One health problem,

since these diseases cause three times as many deaths as cancer, six times as many as accidents, seven times as many as kidney diseases, nine times as many as pneumonia and ten times as many as tuberculosis. From the standpoint of preventability, of course, diseases of the heart and blood vessels rank low in priority; but there are clear indications that this may not always be the case.

In an admirable recent article,[1] Dr. H. M. Marvin, President-Elect of the American Heart Association reminds us that at least five different diseases are grouped under the major heading "diseases of the heart and blood vessels." These are: the conditions grouped under "congenital malformations of the heart"; syphilitic heart disease; rheumatic heart disease; arteriosclerotic heart disease; and hypertensive heart disease, related to high blood pressure. Congenital heart disease is, of course, a relatively small factor of the total problem and syphilitic heart disease is decreasing measurably. It is the last three types which present our major problem.

There are, in general, three major approaches to the control of disease—anti-microbial, nutritional, and therapeutic. All three of these approaches offer definite promise in dealing with one or another form of heart disease. We are as yet in the dark as to the relation of streptococci to rheumatic fever, but it is highly probable that such a relationship exists. Epidemiological control of streptococcosis is a promising avenue here and the use of sulfa drugs after an initial attack of rheumatic fever, the use of penicillin before and after extraction of teeth and operations about the nose and throat and the treatment of bacterial endocarditis by penicillin have yielded encouraging results.

From the approach of the nutritionist and biochemist comes evidence suggesting that obesity and a high blood content of cholesterol are associated with coronary disease and that a saltless diet may be of material value in checking the development of arteriosclerosis.

In the field of therapeutics, treatment of victims of coronary thrombosis with dicumarol has yielded highly encouraging results and several serious malformations of the heart in children may be corrected by surgery.

These are only glimpses of small sections of the problems involved. Dr. Marvin is correct when he tells us "that if this country is to make any significant advance in conquering its leading cause of death, it must be in the first place through wide, intensive, prolonged research by competent investigators who can devote all their time and energies to the task." Hope for the future lies in the program of the National Heart Institute at Bethesda, in the stimulative efforts of the American Heart Association and the studies under way in our universities, particularly the basic work of Ancel Keys on the physiology of the aging process at the School of Public Health in Minneapolis. From the research laboratory must come the knowledge which will bring the controlability of heart disease on a par with its magnitude as a cause of death. If such investigations are adequately supported, a decade—or two decades—of research should make diseases of the heart and arteries a major practical objective for the health officer.

Clearing House on Public Health Salary Information and Personnel Needs

Salaries Are Not the Whole of Recruitment

It is obvious that salaries are not an isolated phenomenon but rather one element in the larger problems of recruitment and personnel needs. It is logical, therefore, that the Clearing House should deal with the other facets of these problems. In this issue therefore, a first step has been taken toward broadening its coverage. It contains some items of significance to recruitment which do not primarily deal with salaries.

The further success of the Clearing House depends on the continued coöperation of the readers of the *Journal*. As has been the case heretofore, contributions dealing with salaries and also significant items dealing with personnel needs and recruitment are invited.

California Does Something About Recruitment

To stimulate recruitment for public health vacancies in California, the California State Health Department has published an appealing 16 page pamphlet entitled: "Thinking about Your Future? What About a Career in Public Health?" It contains a brief summary of the agencies and branches of activity in public health work and devotes individual sections respectively to the jobs of health officer, public health nurse, public health engineer, sanitarian, health educator, public health analyst, and laboratory technician. In each section the activities characteristic of the particular job are described and illustrated by examples and attractive drawings. Salary ranges, training requirements, and the general professional outlook are included. The text is well written and carefully avoids "lingo." The pamphlet is equally suitable for high school students and for those with more advanced education.

A total of 25,000 copies of the pamphlet have already been printed. They are being distributed through the State Department of Education to vocational counselors in high schools, colleges and universities in the state. It is expected that this will be followed by many requests for copies for student distribution which will be handled by the local health departments.

The California State Health Department is unable to send quantities of the pamphlet outside the state. One state has already been granted permission to reprint the pamphlet with a credit line to the California department.

In addition to "Thinking about Your Future," a recruitment pamphlet on physicians in public health is in preparation, planned jointly by the State Personnel Board and the State Health Department. The Health Department is also distributing two one page (quarterly) bulletins containing information on vacancies in public health medical positions, scholarships, and postgraduate public health training, to medical schools and to hospitals in the state approved for intern and residency training.

All in all it looks like an energetic and promising beginning in reducing the personnel shortage in public health positions in California. Yet, California

is not as badly off in this respect as many other states. If these states also would devise and carry out recruitment programs tailored to their individual needs, the shortage of personnel, several years hence, might be less severe than it is now.

DEFENSE SECRETARY CAMPAIGNS FOR MEDICAL PERSONNEL

As of February 15, former U. S. Defense Secretary James Forrestal began a national campaign seeking physician and dentist volunteers for the armed forces. This campaign was proposed by the armed forces Medical Advisory Committee. A campaign committee is made up of the three Surgeons General of the Army, Navy, and Air Force, and serves as a liaison with the American Medical Association, American Dental Association, and other interested professional and non-professional groups.

This campaign for volunteers is said to be preliminary to compulsory induction of such medical and dental personnel. It is based on the fact that there is a pool of 8,000 young men who received their training in whole or in part at government expense and who did not serve in the armed forces, and a further pool of 7,000 who were deferred to continue their training at their own expense

From these two groups it is hoped to recruit as volunteers 2,200 physicians and 1,400 dentists to meet expected shortages by December, 1949.

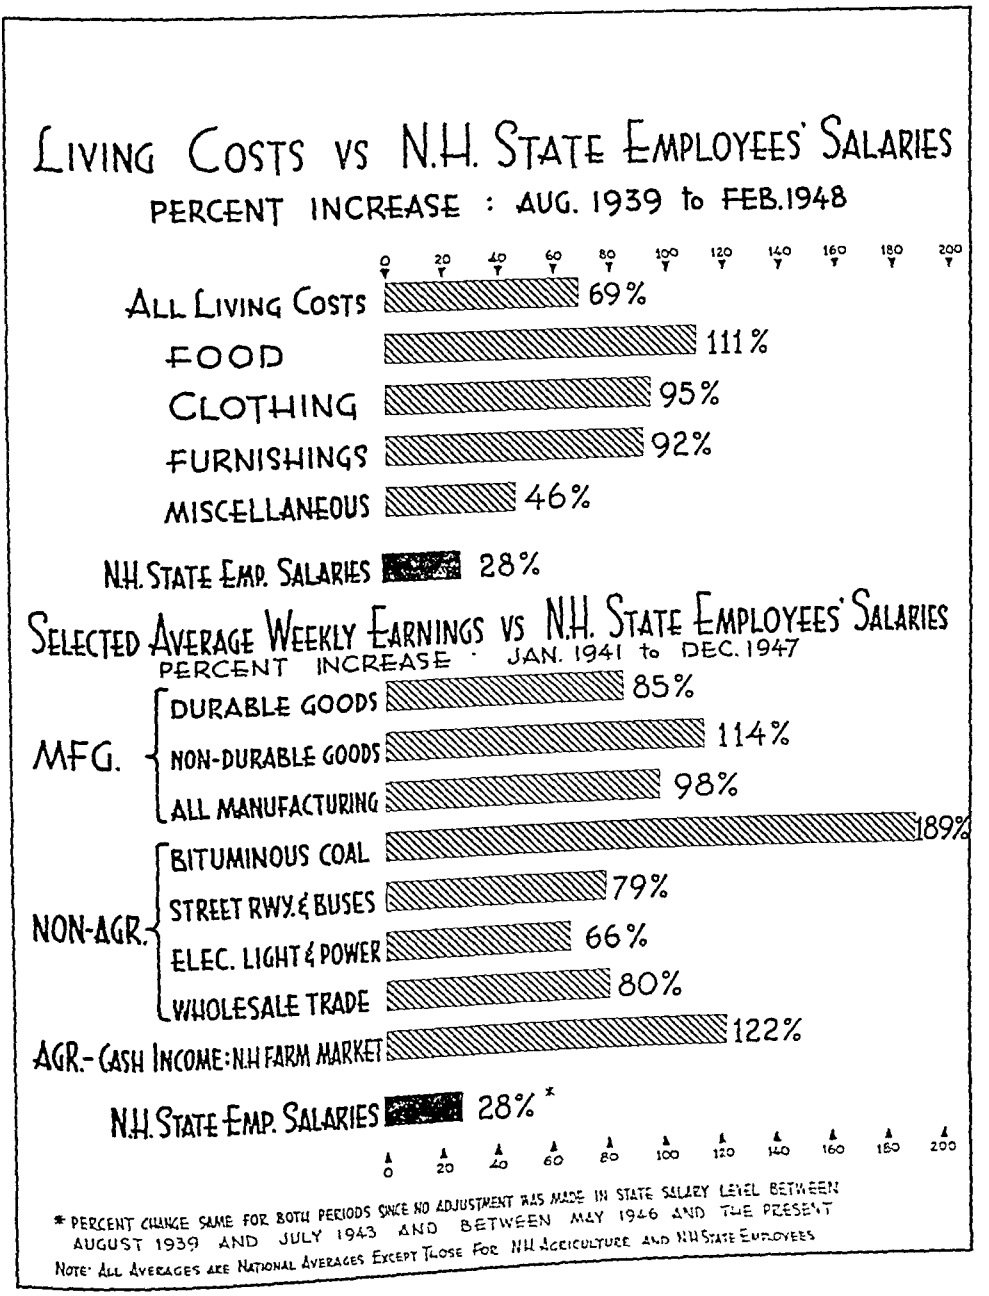
Physicians and dentists are asked to volunteer for a minimum of one year. They would receive $100 a month in addition to prescribed pay and allowances for their rank.

Concurrently with the campaign for volunteers, the Advisory Committee has promised a careful and continuing review of the work load of the medical and dental services and of the utilization of professional personnel to determine where economies can be made.

Obviously this campaign or the compulsory inductions that may follow if it fails to meet its goal, will further reduce medical and dental personnel available for public health agencies. It underlines further the necessity of stepping up recruitment and training programs, of bringing salaries into line, and of a "careful and continuing review of the work load and of the utilization of professional personnel." Perhaps, translated into grass roots terms, that might mean no longer should a medical officer of health carry on for a population of 20,000 a multitude of activities, many of which could well be done by less scarce personnel, leaving him free to give his expert services to 3, 4, or 5 times that population.

HEALTH EDUCATION SECTION SALARY RECOMMENDATIONS

Recommended standards for health educators' salaries have been in progress of development during the past year. At the American Public Health Association's Annual Meeting in Atlantic City in 1947, the Committee on Health Education Planning of the Health Education Section created a subcommittee on salaries for health educational personnel. Its Chairman is Alfred K. George, M.D., of the Department of Preventive Medicine of the University of Cincinnati School of Medicine.



This subcommittee's report, Proposed Levels of Recommended Starting Salaries for Six Grades of Positions for Community Health Educators, was unanimously accepted by the parent committee on Planning for Health Education, in November during the American Public Health Association's Annual Meeting in Boston.

In addition to background information, particularly the varied factors that enter into the determination of appropriate salaries in any specific time or place, the report describes the six grades of positions in terms both of job descriptions and recommended qualifications.

The study is available in mimeograph form for limited distribution from Dr. Alfred K. George, University of Cincinnati College of Medicine, Cincinnati, Ohio.

NEW HAMPSHIRE EMPLOYEES' SALARY BRIEF

The State Employees' Association of New Hampshire has made an interesting approach to the problem of increased salaries for state workers. It prepared a brief for presentation to the General Court which alone has the power to grant increases. Its brief took the form of comparisons between the percentage rise in salaries of New Hampshire employees for the period 1939–1948 and two other factors: the percentage rise in cost of living and the percentage rise

in weekly earnings and of farm income for a somewhat shorter period. One of the charts accompanying the brief is reproduced here. Such a chart might well be adapted for use by public health workers who need to dramatize their salaries in relation to the cost of living.

HOSPITAL SALARIES AND WORKING HOURS

The 4th annual salary survey of the American Hospital Association was recently published. It showed that the typical hospital employee worked fewer hours and received nearly 10 per cent more pay than he did in 1947. His salary had increased by an average of 28 per cent since 1945. The survey, covering more than 4,600 non-federal hospitals gives salary and other information classified by state, size of hospital, size of community, among other details. It is summarized in the February, 1949, issue of *Hospitals,* the Journal of the American Hospital Association, and is presumably available in full from the American Hospital Association, 18 E. Division St., Chicago 10.

SOCIAL WORK EMPLOYMENT CONDITIONS

Social workers, along with teachers and public health workers, have been traditionally in the depressed salary level group. They too are concerning themselves with the salaries and working conditions of their profession.

Under the sponsorship of the American Association of Social Workers, the National Council of Social Work Education, and the National Social Welfare Assembly, the U. S. Bureau of Labor Statistics is conducting a study of salaries and related working conditions among the approximately 50,000 social workers in the United States. It has already completed a pilot survey in Michigan based on about 2,000 returned questionnaires. An analysis of this pilot study appears in the current (April) issue of the monthly *Labor Review* of the U. S. Bureau of Labor Statistics, Washington, D. C.

A NEW STEP IN THE ACCREDITATION PROGRAM

The Executive Board on January 28, 1949, approved the recommendations of the Committee on Professional Education to accredit institutions for Master's degrees other than the M.P.H. (M.A., M.S., M.S.P.H., M.Ed., etc.) with specialization in the field of public health education. This accreditation will be limited to institutions with schools of public health already accredited for the M.P.H. degree. The schools of public health will be in a position to utilize the teaching facilities of closely collaborating university departments and to grant admission to students interested in a career in health education who do not meet the admission requirements for the M.P.H. course but appear otherwise qualified. Below are printed the Criteria for the accreditation of Master's degrees in public health education other than the M.P.H.

It is believed that this step will enable most of the schools of public health to increase materially the number of those students who wish to prepare themselves for a career in public health education. It is hoped that this may be one step in the direction of relieving the shortage of trained community health educators.

Criteria for Institutions To Be Accredited for Master's Degrees other than the M.P.H. (M.A., M.S., M.S.P.H., M.Ed., etc.), with Specialization in the Field of Public Health Education, for the Academic Year 1949–1950 *

1. Candidates admitted for the degree must hold a Bachelor's degree and must have completed at the collegiate level or must include as part of their graduate year, basic academic training in the fields of chemistry, biology, bacteriology, physiology, sociology, psychology, and education.

2. The course for the Master's degree must occupy at least one academic year of which at least half time must be devoted to study in the subject matter areas listed in paragraph 4a, b, and c below.

3. The curriculum must be given in a school of public health accredited by the American Public Health Association or in such collaboration with such a school that the requirements of paragraph 4a, b, and c below are satisfied through utilization of courses in said school or acceptable for credit in said school.

4. The following areas of knowledge should be covered in the graduate course unless credits for previous work acceptable to the institution are presented:

a. Physiological and psychological hygiene (including nutrition and mental hygiene)

b. Microbiology, epidemiology, and sanitation

c. Community health and community organization (including both official and voluntary agencies)

d. Health education (including both public health education and school health education)

* Adopted by the Committee on Professional Education of the American Public Health Association, December 8, 1948; approved by the Executive Board, January 28, 1949.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Essentials of Public Health—*By William P. Shepard, with the Collaboration of Charles Edward Smith, Rodney Rau Beard, and Leon Benedict Reynolds. Philadelphia: Lippincott,* 1948. xviii plus 600 pp. plus 29 charts, plus 19 illus. Price, $5.00.

This volume is unique in the current literature of public health. Dr. Shepard, with the assistance of three colleagues who have contributed important chapters, has set out to present public health, rather than preventive medicine, to medical students and practising physicians. He has attempted to point out the responsibility of the physician and his relationship to the community program.

After an opening chapter which defines the problem of public health and describes the various participating agencies, there follows a series of sections dealing with the modern public health program. Professor L. B. Reynolds and Dr. C. E. Smith contribute an excellent section on environmental sanitation. The discussions of various processes are adequate for the medical practitioner, though far less detailed than is commonly found in many texts. A section on communicable diseases by Dr. Smith is written in quite general terms, leaving the detail for two highly valuable and comprehensive tables. Dr. Shepard discusses tuberculosis, venereal diseases, maternal and child health, school health, adult health, health education and industrial hygiene. Dr. Beard contributes an additional section on occupational health and on statistics.

This is not a text of preventive medicine or of epidemiology. On the contrary, the authors have quite generally assumed that the reader is already familiar with medical details of preventive procedures and have limited their discussions to the aims and operations of community programs. At times they may even have assumed too great a familiarity. Throughout the volume they have stressed the relationship between the physician in private practice and the various agencies participating in the community program, and have pointed out the division of responsibility as well as the basis for coöperation.

Dr. Shepard and his colleagues have succeeded admirably in their chosen task but in doing so have produced a volume of equal if not greater interest to the public health administrator. The latter can read it with real profit to learn his relationship with practising physicians. The book will find its greatest usefulness for health officers and physicians already in practice and for medical students who are reaching the end of their formal schooling. If a book of this character could be read and taken to heart by all practitioners and health officers as they embark upon their respective careers, much of the misunderstanding that now exists could be avoided. GAYLORD W. ANDERSON

Advances in Biological and Medical Physics, Vol. I—*Edited by John H. Lawrence and Joseph G. Hamilton. New York: Academic Press, Inc.,* 1948. 484 pp., illus. Price, $8.60.

Scientists in many categories will find this book useful; to an increasing number it will be indispensable. It is the first issue of a projected annual review: "Each volume will contain from eight to twelve articles surveying the recent progress in radiation research, radiochemistry and tracer methods as applied

to biology and medicine." Though packed with detailed data, the editors found it necessary to omit many important topics for lack of space. Ten chapters by thirteen specialists review "fundamentals of radioactivity, instrumentation, techniques of application and radiation protection."

The opening chapter, by Dr. Lawrence and Dr. Ellsworth C. Dougherty, of the Division of Medical Physics, University of California at Berkeley, summarizes recent work with heavy and radioactive isotopes in clinical and experimental medicine. This is one of three chapters that will be of particular interest to physicians in practice, health officers, industrial physicians, those engaged in certain phases of medical research, and to some industrial engineers. A suggestive part of this chapter is a table of 6 pages listing the important stable and radioactive isotopes that have so far found application in medical research.

Second of these three chapters is by Dr. H. M. Parker on radiation protection and that new area which has been designated as "Health-physics . . . a product of the war-time organization within the Plutonium Project." Dr. Parker defines it as "a borderline subject surrounded by Industrial Medicine, Radiobiology, Industrial Safety, Public Health, Physics, Engineering and Chemistry"! Everyone whose work may expose him to even minimal amounts of radiation could read this chapter with profit to his own and others' safety; likewise health officers, radiologists, industrial physicians, and engineers who are responsible for the safety of exposed personnel.

While much has already been published concerning the effects of the atomic bomb on the Japanese, the chapter by Drs. Joe W. Howland and Stafford L. Warren reviews these facts critically and adds interesting observations made one year later. The latter provide little confirmation of fears as to long-range effects. Possibly the time is still too short.

Material in the seven remaining chapters is of a highly technical nature, often involving extensive mathematical treatment characteristic of nuclear physics. It includes a summary of the nature and production of artificial radioactivity and its measurement, and details of research into fundamental physiology. If one who is untrained in these complexities has the patience to peer beneath the technicalities, he will discover the most exciting news in the world of science. Here man has the tools with which to explore those problems of living matter that have so far baffled his ingenuity, such as certain basic aspects of the metabolism of proteins, carbohydrates, fats, iron and hemoglobin, phospholipids, and nucleic acid derivatives; virus reproduction; antigen-antibody relationships; photosynthesis, etc. Work in each of these fields is reviewed in detail or briefly mentioned. Yet only a beginning has been made. We may say with Prof. A. N. Whitehead: "The whole of human practical activity is in the process of immediate transformation by novelties of organized knowledge."

Format of the book is excellent. Each chapter begins with an outline of its contents and is followed by a bibliography of from 25 to 200 titles. There is an author index of 11 pages and a detailed subject index covering 17 more. An abundance of tables, charts, and formulae will be of practical aid to the specialist. GEORGE S. LUCKETT

Some British Pioneers of Social Medicine—*By Major Greenwood. New York: Oxford University Press*, 1948, 118 pp. Price, $4.00.

Social concern about health is of considerable antiquity. Only rarely, however, were the social relations of health made the subject of theoretical discussion. An instance that proves the rule

is the work of Ibu Khaldūn (1332–1406), North African historian and philosopher, who advanced a number of correlations between such factors as urbanization, diet, occupation, and mode of life, and the health of a population. It was during the 18th century that the need for consideration of social viewpoints in dealing with problems of medicine and hygiene was clearly recognized by medical men. It was left for the 19th century, however, to develop the idea of medicine as a social science and eventually to formulate a concept of social medicine.

In his book, which embodies the Heath Clark Lectures, University of London, delivered in 1946, Major Greenwood deals with certain aspects of this development in Britain. Admitting that he is more interested in social statistics than in administration or legislation, the author focuses attention chiefly on the contributions of certain British pioneers of social medicine who were interested in discovering by means of statistics the facts concerning the health of the society in which they lived. Greenwood traces the development of this line of thought in a series of selected biographical sketches from the 18th century to the close of the 19th century.

After appraising the work of John Graunt, William Petty, and Thomas Short, he discusses the activities of Thomas Percival and John Ferriar in Manchester. Separate chapters are then devoted to Edwin Chadwick, William Farr, John Simon, and the last chapter deals with Florence Nightingale and Francis Galton. Those familiar with Greenwood's other writings will know that these essays by a wise man, who has a great liking for "men who loved doing little sums," are written in delightful English. Of the two appendices, that entitled "The Epidemiological Future" is a must for every epidemiologist and health officer. It is unfortunate that the price of $4.00 should be set for this small book, as it is one that teachers might otherwise well urge students to buy. GEORGE ROSEN

Your Diet for Longer Life—*By James A. Tobey. New York: Wilfred Funk,* 1948. 280 pp. Price, $3.50.

"Good nutrition makes life worth living" is, in the author's phraseology, the theme of this handy reference book by a well known authority on health, in language addressed to the intelligent layman who is seeking help to maintain his vigor and vitality in later years. The scientific basis for good nutrition is simply and clearly explained.

The author's special emphasis on weight control through diet is in line with the best medical opinion that obesity predisposes to many of the chronic ills of middle and later years. Special dietary advice is given for several other abnormal conditions, as well as for the expectant and nursing mother. The author supports each recommendation with accepted scientific facts. The only criticism might be that he is more technical on certain subjects than others, and than is necessary to make his point. In a few instances he seems too ready to accept data not fully substantiated by other workers. The questions at the end of the chapters are not particularly stimulating and, in some instances, are rather vague.

In general, this little book is readable, scientifically sound, and a convincing exposition of the importance of good nutrition for a longer and fuller life.

HELEN S. MITCHELL

Introduction to Health Education—*By Jackson R. Sharman. New York: Barnes,* 1948. 273 pp. Price, $3.00.

"If teachers are to assume the important responsibility of educating all boys and girls in healthful ways of living, their preparation must cover at least the minimum essentials of health education. This book was prepared for use

in courses on health education for the general classroom teacher who can complete only one or two courses in the philosophy, subject matter, and methods of health education."

This book does meet the objectives set by the author. The philosophy which underlies the discussion throughout is in keeping with current thinking regarding the school health program.

Three broad areas are covered by the eleven chapters: background; school environment, health education curriculum, and principles of method in health education; and basic subject matter in health education.

The questions at the end of each chapter are provocative and should be of considerable assistance to the students. The references which follow each chapter are up-to-date and are culled from a wide field.

The paper, type size, printing, and format are in good taste and make for easy reading.

There are a few minor errors of fact, but on the whole the material is scientifically accurate.

Instructors of health education in the teachers colleges and schools of education will find this textbook of assistance in their introductory courses in health education. S. S. LIFSON

New Techniques of Happiness—*By Albert Edward Wiggam. New York: Wilfred Funk, Inc.*, 1948. 352 pp. Price, $3.75.

If we accept the meaning of health defined by the recent National Health Assembly as being "a state of complete physical, mental and social well-being," the above book is within the scope of public health. It is not concerned with abstract philosophy but is a digest of recent experiments and studies by outstanding psychologists concerned with finding more adequate social techniques. Dr. Wiggam, a distinguished science reporter, translates the findings of these scientists, comments on them, and points the way for the reader to use such findings in order to obtain greater happiness and contentment of mind. It is in this interpretation that the author himself gives a generous sprinkling of his own wholesome philosophy.

Some outstanding chapters are: How To Conquer Fear and Worry, How To Manage Your Emotions, and How To Get along with People. The studies on relaxation made in the Laboratory of Clinical Physiology, University of Chicago, are reported in some detail. The chapter, A New Way To Cure Bad Habits is so challenging that the reader may be tempted to try this new method of "negative practice."

While this book makes no attempt to approach the study of human conduct through psychiatry, it is nevertheless a readable digest of practical, applied psychology for both professional and lay readers. JEAN V. LATIMER

American Standard Practice for School Lighting—*New York: The Illuminating Engineering Society*, 1948. 77 pp., 45 illus. Price, 1 to 4 copies, 50¢ ea.; next 20 copies, 25¢ ea.; all over 24 copies, 15¢ ea.

The *American Standard Practice for School Lighting* is published under the auspices of the American Standards Association with the Illuminating Engineering Society and the American Institute of Architects serving as co-sponsors. It encompasses and provides specific recommendations for the many features of a classroom which constitute the visual environment for the students. For the first time in a publication of this type, specifications as to maximum fixture brightness and limiting brightness ratios, in addition to foot candle tables, are set forth to assure comfortable and easy seeing conditions in the classroom. Recommended reflectance values for desks, floors, wall, and ceiling are given which, with a good distribution of light,

will assure properly balanced brightnesses between these areas in the classroom. Illumination results to be expected from a considerable number of lighting installations, employing both incandescent and fluorescent sources, are indicated. The control and use of natural lighting is discussed. The relative merits of various fenestration techniques and daylight controls, including directional glass blocks and diffusing screens, are also set forth. The importance of adequate wiring for today's and tomorrow's needs are stressed in an Appendix, and the proper wire sizes are suggested for typical conditions to serve as a guide for the school architects.

The report is generously illustrated with photographs and charts. An extensive bibliography is also included. It should be of particular value to school administrators, building superintendents, members of environmental divisions of public health staffs, and school architects.

FRANCIS B. ELDER

Handbook of Practical Bacteriology—*By I. J. Mackie and J. E. McCartney (8th ed.). Baltimore: Williams & Wilkins,* 1948. 624 pp. Price, $7.00.

This handbook by English authors is a well-bound book on a fair grade of paper. The contents of the book extends from "Practical Bacteriology" to include, as indicated in the opening line of the first chapter, Bacteriology or Microbiology, which are obviously not synonymous.

In reading this very good book, one is impressed once again with the need of uniformity in terminology on a global basis; to mention only one example, such as "Bacillus" which is recognized by the authors on page 12.

It seems to the reviewer that bacteriology is definitely one field, viruses another, pathogenic fungi another, protozoa another—thus seven pages devoted to pathogenic fungi seems an injustice, even though the authors refer to other texts for detailed information. For a text on practical bacteriology, *per se,* future revisions might well follow expansion on the practical side and minimize the general textbook consideration.

Among many worth while features of this text, the reviewer directs attention to the chapter on microscopy as an excellent one. The fine chapter on culture media is an extensive and varied one, including such media as Lowenstein-Jensen Medium for cultivation of *Mycobacterium tuberculosis.* This particular medium is currently receiving deserved special emphasis at the United States Public Health Service Tuberculosis Evaluation Laboratory under Dr. Martin Cummings.

The text can be recommended for use as the authors indicate to those who have used its predecessors and further to those interested in a viewpoint, expression and approach somewhat different from that currently found in most texts by American authors.

F. C. LAWLER

American Nurses Association Public Relations Workshop—*A Manual of Practical Public Relations Techniques for the Guidance of the National Membership of the American Nurses Association. New York: American Nurses' Association,* 1948. 32 pp., 39 illus. Price, $2.50.

As indicated by the title, this manual was prepared for the membership of the A.N.A. and particularly for the chairman of Public Relations Committees of the state and district nurses' associations. Anyone, nurse or non-nurse, who is not familiar with how to use publicity media will find this manual helpful. It was prepared by Edward L. Bernays, Counsel for Public Relations for the A.N.A. He defines public relations and then explains its techniques in a very understandable way. Charts and photo-

graphs are used to illustrate his points and make the manual very easy reading.

The public health agency that does not have a trained, experienced public relations member of its staff might well buy a copy of this manual as an aid to those who are responsible for interpreting its work to the public. It tells how to approach newspaper editors, radio and television station program chairmen, and movie managers, and the kind of information that will interest them. The last chapter, Your Community Blueprint, should be particularly helpful to the young public health worker as it summarizes community groupings and suggests how to use them for interpretation purposes.

EMILIE G. SARGENT

Danger! Curves Ahead — *By Miriam Lincoln. New York: Macmillan,* 1948. 138 pp. Price, $2.50.

"This little volume on obesity has been prepared as an aid to those courageous souls who, realizing that they are overweight, have determined to do something about it but need guidance on procedure." This statement by the author in her introduction is really the theme of the book.

Obesity, its causes, dangers, and best methods of correction are discussed in a simple and interesting style. The reader is advised how to overcome some of the psychological handicaps of reducing successfully. Insight into the patient's emotional problems, anxieties, and frustrations is a specialty of the author in handling her patients.

The book is obviously addressed to overweight women and makes an appeal to pride in appearance, as well as to health. The nutritional advice given is sound but rather too brief for those with inquiring minds. The simple table of calorie values of foods and well planned reducing menus for different seasons of the year should be helpful. A unique feature is the list of low-calorie company menus for use when entertaining one's obese friends.

The reviewer does not hesitate to recommend this little volume to any woman without scientific background who is interested in maintaining, or re-establishing, her normal weight for her height and build.

HELEN S. MITCHELL

Emergency Maternity and Infant Care—A Study of Administrative Experience — *By Nathan Sinai and Odin W. Anderson. Ann Arbor: School of Public Health, University of Michigan. Bureau of Public Health Economics Research Series No. 3,* 1948. 181 pp.

This is the report of an administrative study of the Wartime Emergency Maternity and Infant Care Program. Being one of six national health plans which have been inaugurated in the United States during the past ten years, the authors regard EMIC as an "experimental laboratory," from which there are lessons to be learned. Most of the problems encountered in EMIC are inherent in any state or national health plan for the distribution of medical and hospital care, whether on a voluntary or compulsory basis.

In Part I, the authors tell the story of the hurried establishment and somewhat stormy career of EMIC. Many of the reasons for the confusions, tensions, and frustrations experienced by those intimately involved in the administration of the program and rendering services under its provisions, are analyzed. The scope of this huge undertaking and the size of the job accomplished are indicated.

For students in medical administration, Part II will be found to contain much valuable information. Such problems as methods of payment for physicians' and hospital services, the means test, and administrative controls are discussed in terms of the general prob-

lem and current practice in various past and existing plans as a background for the EMIC experience.

Here is material which present and future medical care administrators need to get their teeth into, while the medical care philosophers argue about the future. JESSIE M. BIERMAN

International Approaches to Problems of Undeveloped Areas—*Papers presented at the Round Table on Undeveloped Areas, 1947 Annual Conference of the Milbank Memorial Fund, New York.* 76 pp. Price, $.25.

One of the round tables at the 1947 Annual Conference of the Milbank Memorial Fund considered the demographic background of problems of undeveloped areas and the steps which might be taken in an international approach to these problems as they concern economic development, rural industrialization, and health aspects "in the social evolutionary perspective." Participants included Frank W. Notestein, Henri Laugier, David Weintraub, Leonard B. Rist, Samuel H. Thompson, William P. Forrest and Sir Raphael Cilento.

A specific application of general principles was focused on research and policy in Puerto Rico. Kingsley Davis and Rexford Guy Tugwell were the speakers.

The report develops the theme that genuine world prosperity is indivisible. Good coördination and team work among the different agencies and specialists concerned is necessary for the international approach to these problems. Solutions cannot be imposed from without; they must come from within. REGINALD M. ATWATER

Food Products—*By Henry C. Sherman (4th ed.). New York: Macmillan,* 1948. 428 pp. Price, $4.80.

As a sequel to Sherman's standard text *Chemistry of Food and Nutrition,* the present freshly revised volume is doubly welcome. The book adequately covers the subject matter for a broad general study of foods and food adjuncts. As stated in the preface, "For nearly all of us, food is the largest item in the cost of living and usually the most potent factor in the influence of daily habits upon health. Wise use of food thus means much for satisfaction and welfare. And to use food wisely one should have a fairly wide knowledge of food products."

The 15 chapters consider the several types of foods—fresh, and processed—from the points of view of production, composition, processing, and economics. As one would expect, the author interjects freely much material on nutritive value and dietetics. This adds materially to the value of the book. Each chapter is followed by a list of well chosen suggested readings and reference material. The book closes with an excellent chapter on The Problem of the Best Use of Food: with Some Aspects of Food Economics. A *must* for nutritionists and dietitians, and strongly recommended for physicians, nurses, and public health officials who need a handy reference on food products.

CARL R. FELLERS

Man-Made Plague, A Primer on Neurosis—*By William G. Niederland. New York: Renbayle House,* 1948. 298 pp. Price, $3.50.

This book of only 300 pages presents a very readable and scientific approach to "the great malaise of our time—nervous ailments which have become the most frequent cause of ill-health among civilized men." It comprises ten chapters, among which are: Signals–Symptoms–Sufferings; Neurosis: The Hidden Pain; Problems of Life and Love. Unlike most writers on these topics the author goes directly to the point of what he means, avoiding polysyllabic chatter and expressing his thoughts in

plain, simple language which an intelligent layman can understand. The reader is carried along with a flow of thought from a scholarly and independent thinker who has a first-hand knowledge of human beings as they live and strive in something called social organization. Familiar with psychiatric and psychoanalytic therapies, Dr. Niederland does not proclaim each or any as sales talk panacea. *Man-Made Plague* is a book that should be in the right-at-hand office library of every practising physician, health officer, nurse and social worker.

ESTHER LORING RICHARDS

Practical Bacteriology, Hematology and Parasitology—*By E. R. Stitt, Paul W. Clough, and Sara E. Branham (10th ed.). Philadelphia: Blakiston,* 1948. 989 pp. Price, $10.00.

After approximately forty years and ten editions this book still maintains its place of leadership as a practical reference book in the fields of bacteriology, parasitology, hematology, and clinical pathology. The phenomenal developments of the decade that has elapsed since the previous edition has necessitated extensive reworking of this treatise. The authors have deleted much outdated and less important material in favor of extensive additions of the newer developments in the various fields, particularly in the case of viruses and rickettsiae. They have called upon numerous specialists in the various fields to review the various sections to the end that an authoritative, accurate, and encyclopedic yet eminently practical volume has been produced.

This tenth edition consists of 989 pages divided into the four general subject headings noted above, plus a preface, and an appendix which is packed with useful information concerning laboratory reagents, apparatus, and procedures, together with an excellently arranged and usable index.

As an indication of the current nature of the material in this edition it should be noted that the bacteria taxonomy of the 6th edition of *Bergey's Manual,* which was published about the same time as this book, is used throughout. As in previous editions, the volume is replete with excellent diagrams, charts, tables, illustrations, and photographs. A number of the latter, particularly in the hematology section, are in color.

The book is well printed and firmly bound so that it should stand the rigors of laboratory use. Every public health and medical diagnostic laboratory should have this standard reference book immediately available. It will also be found invaluable by workers in any of the fields of communicable disease control.

M. H. MERRILL

Practical Therapeutics, A Course in—*By Martin Emil Rehfuss, F. Kenneth Albrecht, and Alison Howe Price. Baltimore: Williams & Wilkins,* 1948. 824 pp. Price, $15.00.

This book contains 824 pages of practical, readily usable information in therapeutics. It is a ready reference book for the medical student and for the busy practitioner. A short, concise opening chapter discusses the fundamental problems of modern therapy. The second section is devoted to a very thorough discussion of symptomatic therapy in which the differential diagnosis is presented and treatment for the relief of symptoms offered. Many old and new remedies are briefly, yet completely described. In Section Three the various disease entities as encountered in clinical medicine are given, followed by complete therapeutic directions. A fourth section deals with special treatments. The breadth of the subjects discussed is amazing. No important type of treatment is too insignificant nor any too complex to receive a place in this book.

All forms of therapy are completely

and well presented. Modern drugs, antibiotic agents, radiation, radioisotopes, psychosomatic measures, physical medicine, occupational training, and even nursing care are covered in outline style. The authors leave no room for doubt as to the indications for each drug, the dosage, method and frequency of administration, as well as the results to be anticipated.

The format of the book, the large type, the outline presentation and very complete index make the contents readily and quickly available to the busy practising physician.

GEORGE C. GRIFFITH

Health and Physical Education for Junior and Senior High Schools —*By David K. Brace. New York: Barnes,* 1948. 392 pp. Price, $4.00.

After a brief section on the organization and administration of programs in health education, physical education, recreation, and safety education, this book is devoted almost entirely to a series of short teaching units in health and physical education.

Many teachers will find this volume to be quite helpful in terms of guidance as to objectives, content, procedures, pupil activities, and evaluation of results gained from various suggested learning experiences.

In any attempt to cover two such broad fields as health education and physical education in a single small book it is inevitable that significant problems in both fields will be omitted. In this volume, however, the author covers a great deal of ground because the units presented are very concise and in outline form.

The author should bring his bibliography up-to-date, as many of the references and films cited are too old to give the reader a modern concept of problems in the field of health education. On page 369, for example, health books published in 1919, 1924, and 1928 are included, as are numerous references published in the 30's. New and significant developments come so rapidly in the field of health that these volumes cannot possibly present a current picture. Except for this weakness, the book should be helpful to health educators and physical educators alike.

OLIVER E. BYRD

Blood's Magic for All—*By Alton L. Blakeslee. New York: Public Affairs Committee, Inc.,* 1948. 32 pp. Price, $.20.

This pamphlet presents the story of blood in an unusually clear, well paced and complete fashion which makes excellent reading for lay or professional persons. It describes the development of our knowledge of blood and its components; the functions which these components serve; the various useful products made from blood; the ways in which these products can aid in the medical care of Everyman; the unmet problems and future advances which research on blood will resolve; and finally the story of the ways in which blood has been made available, and the tremendous project undertaken by the American National Red Cross to make blood and blood products available throughout the United States. All this is told with scarcely a flaw in fact or in emphasis, although one might wish that mention had been made of the civilian blood and plasma programs in many of our states, which preceded and laid the practical foundation for the present national program. The pamphlet may be heartily recommended to all health workers—and indeed to all citizens—since "Human blood today is a public health measure . . . It cannot be made synthetically. The only source of supply is the blood bank of human veins . . . The giving (of blood) gives you a personal share in fighting death and disease, in promoting public health. It makes you an active partner in the progress of medicine." GEOFFREY EDSALL

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ALLERGY. WHAT IT IS—WHAT TO DO ABOUT IT. *Harry Swartz.* New Brunswick, N. J.: Rutgers University, 1949. 203 pp. Price, $2.75.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Best Foot Forward—It is often a rewarding experience to see our native ways of doing things exposed for foreign examination. You will not be disappointed in this portrayal of our exuberant health educational activities reported by one of us who knows them inside and out. They are peculiarly American and we like them, he says.

BAUER, W. W. Health Education in the United States. Health Education J. (British) 7, 1:7 (Jan.), 1949.

On Our Way—We are progressing in our American studies of the efficacy of BCG. In the New York State plan, immunization is being extensively used with tuberculin-negative reactors who are occupationally exposed — nurses, medical students, hospital personnel.

BIRKHAUG, K. E. New Developments in BCG Vaccination. New York State J. Med. 49, 4:401 (Feb. 15), 1949.

Department of Semantics—What unfathomable gulfs exist in meanings of some plain English words as they are used on the opposite sides of the Atlantic Ocean! Across the water "social medicine" are words of distinction. Here they are something to be spat out at an adversary. Discussing postgraduate training for public health, this Britisher suggests a "diploma in social medicine." Imagine the consequences hereabouts.

BROCKINGTON, F. Social Medicine in Great Britain. Canad. Pub. Health J. 40, 1:22 (Jan.), 1949.

To Clear Away Some Confusion—Principally because it appears outside the usual run of bacteriological, medical or public health journals, your attention is called to this committee's opinion about what is, and what isn't, polio virus.

COMMITTEE ON NOMENCLATURE (NFIP). A Proposed Provisional Definition of Poliomyelitis Virus. Science 108, 2817:701 (Dec. 24), 1948.

As a Part of Social Security—What will interest you most—once you've recovered from your first amazed comprehension that this matter-of-fact account is describing the very same service depicted by most Americans as the hideous invention of the old Nick himself—is the change in local public health activities under the (British) National Health Service Act. Local health authorities will continue to administer maternal and child health projects, public health nursing services, immunizations, and special tuberculosis control and mental health activities, though they are relieved of hospital administration.

DAVIS, B. M. The British National Health Service. Pub. Health Rep. 64. 6:161 (Feb. 11), 1949.

Things We Don't Know about Pneumonia—On the reasonable assumption that what I can understand will be readily intelligible to all health workers, and may prove of interest to them as well, I thumb the specialty journals — bacteriological, immunological, etc.—in search of papers of use to others than the specialists. This one is about immunological paralysis. It proved to be somewhat beyond my depth but if you can keep afloat, you may get some new insight into the difficulties that plague researchers in pneumonia prophylaxis.

FELTON, L. D. The Significance of Antigen in Animal Tissues. J. Immunol. 61, 1:107 (Jan.), 1949.

A Simply Must—Maybe it's no more than just a sign of our own *Jour-*

nals' broad-mindedness, but this Annotated Bibliography's chief function seems to be to tell you about topnotch papers in rival scientific publications. Do not fail to read this one! Not only is it bread and butter, but it's dessert, too—nutritious orientation in an important social problem plus delectable writing! After discussing the way most Americans marry, divorce, and remarry, and behave in between, the writer comments, "They are amazingly legal about their immorality."

HILL, R. The American Family. Pub. Health Nurs. 41, 1:3 (Jan.), 1949.

Not To Be Read While Running—Quote. Perhaps the most exciting single event relative to human nutrition during the past year has been the isolation of vitamin B_{12} Unquote. For details of excitement see concentrated, capsule review.

KING, C. G. New Advances in the Science of Nutrition. J. Am. Dietet. A. 25, 2:109 (Feb.), 1949.

Epidemiologic Evidence—It seems that faulty plumbing must have been wildly imputed by persons unnamed to be responsible for the spread of polio. Two U.S.P.H.S. officers underscore the groundlessness of the accusation. Though other means cannot be ruled out, person-to-person contact is assumed to be the usual way the disease is spread, they say.

KRUSE, C. W., AND QUINBY, G. E. Plumbing Is Not Guilty of Polio. Plumbing and Heating 11, 6:24 (Jan.), 1949.

Nutrition is More Than Meals—Environment determines largely the state of nutrition and influences the incidence of malnutrition as well as its characteristics and manifestations. Environment also alters dietary requirements. That's the best I can do at reducing 90 pages of text to a couple of sentences. It's not any too revealing, is it? Well, try your hand at it.

KRUSE, H. D. A Concept of the Etiological Complex of Deficiency States with Especial Consideration of Conditions. Milbank Quart. 27, 1:5 (Jan.), 1949.

Answer: Tight Ones Do—To help determine whether gauze face masks do much good, rabbits (some covered with gauze masks, some uncovered) were exposed to an atmosphere heavily saturated with virulent bovine TB. There was a 90–95 per cent reduction of incidence of infection among the masked animals. Under normal exposure the protection might be expected to be complete.

LURIE, M. B., AND ABRAMSON, S. Do Masks Protect? Am. J. Nurs. 49, 2:100 (Feb.), 1949.

Something They Drank?—There wasn't enough milk to go round, so the enlisted men got only a ladle full on their morning cereal. What was left in the serving dishpan was then decanted into pitchers and later served to officers—as much as they wanted to drink. An explosive outbreak of polio occurred. One in 188 of the enlisted men came down with the disease. One in every 19 of the officers was attacked; and their infections were much more severe. Are you thinking what I'm thinking?

MATHEWS, F. P. Poliomyelitis Epidemic Possibly Milk-Borne in a Naval Station, Portland, Oregon. Am. J. Hyg. 49, 1:1 (Jan.), 1949.

Interesting Facts Department—At the peak of a polio epidemic only two species of blow flies, among all that were trapped, yielded positive tests for polio. Two weeks later house flies, flash flies, and the black blow fly were infected. Then came a spell when no flies carried polio, and as the epidemic subsided one species of blue bottle fly became positive again.

MELNICK, J. L. Isolation of Poliomyelitis Virus from Single Species of Flies Collected during an Urban Epidemic. Am. J. Hyg. 49, 1:8 (Jan.), 1949.

Now They Sterilize First—Six laundry workers who handled soiled linen from a laboratory where research with Q fever was carried on came down with the disease. Seven fellow employees in the laundry, who had no contact with the linen, remained free of infection.

OLIPHANT, J. W., *et al.* Q Fever in Laundry Workers, Presumably Transmitted from Contaminated Clothing. Am. J. Hyg. 49, 1:76 (Jan.), 1949.

Anent Rod-Sparing and Child-Spoiling—This may not be as new and unusual as I think it is, but still it should be brought to your eyes. In Rochester a letter was sent to all mothers of 2½ year olds inviting them to bring the youngsters to the Health Institute for a check-up which constituted a Revised Stanford-Binet test plus interpretive advice. For what happens thereafter, see paper.

ROBERTS, K. E., AND ALLDRICH, C. A. A Program To Foster Adjustment in Young Children. Pediatrics 3, 2:195 (Feb.), 1949.

Good News—Though this is therapy it is a concern of preventive medicine. A small number of cases of primary, atypical, non-bacterial pneumonia responded well to treatment with aureomycin. The rickettsias and some of the viruses, apparently, have at last found their chemotherapeutic come-uppance.

SCHOENBACH, E. B., AND BRYER, M. S. Treatment of Primary Atypical Non-Bacterial Pneumonia with Aureomycin. J.A.M.A. 139, 5:275 (Jan. 29), 1949.

Here's A What-Dun-It? For You—From a slum area in Stockton-On-Tees a group of people was moved to a new housing project. During a five year period a check was kept on the health of the happy 710. Standardized death rates among the fortunate ones rose materially and were consistently higher than among the unfortunate controls who remained in the slums. Can you figure out a reason?

SHANK, R. E. Nutrition in Preventive Medicine. Nutrition Rev. 7, 1:1 (Jan.), 1949.

Not Yet Foolproof—Of first importance to child hygienists is this study of a very small number of serious reactions following pertussis vaccination, and the ways by which even this minute fraction of unhappy endings among all the army of protected children might have been avoided.

TOOMEY, J. A. Reactions to Pertussis Vaccine. J.A.M.A. 139, 7:448 (Feb. 12), 1949.

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Luis Alverez, Jr., M.D., 1441 Fernandez Juncos Ave., Santurce, P. R., Director of Public Health Unit, Catano, P. R.

Capt. M. J. Aston, (MC) USN, Naval Medical School, Bethesda 14, Md., Medical Officer in Command

Ann McAvoy Birch, M.D., 749 Washington St., New York 14, N. Y., Health Officer-in-Training, City Health Dept.

Charles A. Bourdon, M.D., M.P.H., 775 Gosford St., City Mall Annex, Montreal 1, Que., Canada, Special Officer and Chief of Health Districts, City Health Dept.

Charles E. Brenn, M.D., 227½ West 4th St., Owensboro, Ky., Health Officer, Owensboro-Daviess County Health Dept.

George M. Brother, M.D., M.P.H., 1098 West Michigan St., Indianapolis 7, Ind., Director of Preventive Medicine, State Board of Health

Dorothy B. Chamberlin, M.D., Housatonic, Mass., Apprentice Epidemiologist, New York State Health Dept.

Tracy Jones, M.D., 620 South Third, Louisville 2, Ky., Asst. State Health Commissioner, State Dept. of Health

Leo A. Kaprio, M.D., M.P.H., Abrahams St. 15 b A 11, Helsinki, Finland, Health Officer, Province of Uusimaa Health Dept.

M. Catherine Magee, M.D., 132 E. 45th St., New York 17, N. Y., Candidate for M.P.H., Columbia Univ. School of Public Health

G. P. Morison, M.D., Professional Bldg., Charlestown, W. Va., Director, Tri-County Health Dept.

Thomas R. Perdue, M.D., 1606 Linwood, Parsons, Kans., Asst. Health Officer, Labette County Health Dept.

A. E. Raitt, M.D., M.P.H., 215 5th St., Colusa, Calif., Health Officer, Colusa County Health Dept.

Huston K. Spangler, M.D., Belmont Hospital, Worcester, Mass., Superintendent

H. F. Wilkins, D.V.M., Capital Station, Helena, Mont., State Veterinarian of Montana

Laboratory Section

Philip R. Edwards, Ph.D., U.S.P.H.S., 605 Volunteer Bldg., Atlanta, Ga., Bacteriologist in charge of Enteric Bacteriology Laboratories, Communicable Disease Center

Thomas P. Galarneault, Jr., 716 South Ashland Blvd., Chicago 12, Ill., Graduate Student of Bacteriology, Loyola Univ.

Dorothy J. Granger, 5960 Chabolyn Terrace, Oakland 18, Calif., Public Health Laboratory Technician, Alameda County Health Dept.

Lewis W. Jones, Utah State Agricultural College, Logan, Utah, Asst. Professor of Bacteriology

Elfriede Klaucke, 249 Belmont St., Worcester, Mass., Asst. Bacteriologist-Serologist, City Health Dept.

Edwin H. Lennette, M.D., Ph.D., 1392 University Ave., Berkeley 2, Calif., Chief, Viral and Rickettsial Disease Laboratory, State Dept. of Public Health

Milford N. Lunde, M.P.H., 1716-A E. Washington St., Charlestown, W. Va., Junior Bacteriologist, State Hygienic Laboratory

Arthur A. Rosenberg, M.S., Venereal Disease Research Lab., U.S.P.H.S., Staten Island, N. Y., Serologist

Luis A. Rubio, 172 Villamil St., Santurce, P. R, Student of Medical Technology, School of Tropical Medicine

Doris V. Shay, 614 Willow, Trinidad, Colo., Bacteriologist, Branch Laboratory, State Board of Health

Bernice S. Stevens, 300 Hall Ave., Jamestown, N. Y., Bacteriologist in charge of Serology, Jamestown Municipal Laboratory

Statistics Section

Jewel E. Godwin, M.A., 2122 California St., Apt. 655, Washington 8, D. C., Health Program Representative, U. S. Public Health Service

William Holland, LL.M., 1 Madison Ave., New York, N. Y., Medical Statistics Analyst, Metropolitan Life Insurance Co.

Elizabeth H. Jackson, Ph.D., 420 West 116 St., New York, N. Y., Research Staff Member, Milbank Memorial Fund

Robert S. Levin, 1 Madison Ave., New York, N. Y., Accident Statistics Analyst, Metropolitan Life Insurance Co.

Mary S. Louie, 2114 14th Ave., Oakland 6, Calif., Public Health Statistician, Alameda County Health Dept.

Samuel C. Marcus, 1746 Hobart St., N. W., Washington, D. C., Biostatistician, National Institutes of Health

Marian M. Martin, 710 S. W. St. Clair, Portland 5, Ore., Statistician, State Board of Health

Edith H. Rafton, 1 Madison Ave., New York, N. Y., Supervising Medical Statistics Asst., Metropolitan Life Insurance Co.

Doris M. Strail, 4321 North Mozart St., Chicago 18, Ill., Statistician-Supervisor, Tuberculosis Institute of Chicago and Cook County

Margaret C. Taylor, 8607 Piney Branch Rd., Apt. 103, Silver Spring, Md., Consultant on Medical Records, Medical Research Statistics Division, Veterans Administration

Engineering Section

James A. Anderegg, M.S., 64 Westgate, Cambridge 39, Mass., Asst. in Sanitary Engineering, Massachusetts Institute of Technology

Lambert B. Cain, 900 East 77th Terrace, Kansas City, Mo., Public Health Engineer, City Health Dept.

Konchady Dayananda, S.M., % Dr. Abel Wolman, Johns Hopkins Univ., Baltimore 18, Md., Student

Solomon Galler, 261 East Way, Brooklyn 29, N. Y., Health Inspector, New York City Health Dept.

Eli Glogow, 474 So. La Peer Drive, Beverly Hills, Calif., Student, Univ. of California at Los Angeles

Albert Grego, 1120 West Maine Ave., Baldwin Park, Calif., Junior Sanitarian, Los Angeles City Health Dept.

John P. Lynch, West Parish Filters, Westfield, Mass., Chemist and Bacteriologist, Springfield Water Dept.

Henry L. Roahrig, 240 Peabody St., N. W., Washington 11, D. C., Sanitary Engineer, U. S. Public Health Service; Exec. Secy., Sanitation Study Section, National Institutes of Health

H. L. Thomasson, 1098 W. Michigan, Indianapolis, Ind., Public Health Sanitarian, State Board of Health

Albert Q. Y. Tom, M.S., 8 Homer St., Brookline, Mass., Research Assoc., Massachusetts Institute of Technology

Wilbur J. Widmer, M.S., Box U-37, Dept. C.E., Univ. of Connecticut, Storrs, Conn., Instructor of Civil Engineering

Wallace S. Zeray, 25 Pent Highway, Fairfield, Conn., Sanitarian, Norwalk Health Dept.

Industrial Hygiene Section

Louis F. Garber, M.P.H., 813 Moreau Drive, Jefferson City, Mo., Public Health Engineer, State Division of Health

Capt. Vincent Hernandez, (MC), USN, Naval Medical School, Bethesda, Md., Exec. Officer

Mary-Elizabeth H. Kent, M.D., 1411 North Gregson St., Durham, N. C., Asst. Director, Employee's Health Service, American National Red Cross

Pablo P. Recarte, M.D., M.P.H., Banco de Seguros del Estado, Calle Agraciada, Montevideo, Uruguay, S. A., Chief, Service of Industrial Hygiene

Adolph W. Schmidt, M.B.A., 525 William Penn Place, Pittsburgh 30, Pa., Vice-President and Governor, T. Mellon & Sons

Food and Nutrition Section

Conrado F. Asenjo, Ph.D., School of Tropical Medicine, San Juan, P. R., Head, Dept. of Chemistry and Nutrition

Graciela Delgado, Box 913, Mayaguez, P. R., Nutritionist, P. R. Public Health Service

Zean Gassmann, 160 North LaSalle St., Chicago 1, Ill., Supt., Division of Foods and Dairies, Illinois Dept. of Agriculture

Cora J. Northington, Health Center, Dalton, Ga., Nutritionist and Health Educator, Dalton-Whitfield County Health Dept.

Agnes Schulz, 3400 N. Eastern, Oklahoma City, Okla., Nutrition Consultant, State Dept. of Health

A. P. Stewart, Ph.D., 425 Battery St., San Francisco, Calif., Research Administrator, Golden State Co., Ltd.

Maternal and Child Health Section

Marion G. Josephi, M.D., 2629 Dwight Way, Berkeley, Calif., Child Health Consultant, State Dept. of Public Health

Geraldine Piper, M.S., 3400 N. Eastern, Oklahoma City, Okla., Nutrition Supervisor, State Dept. of Health

Jean B. Sweeley, M.S.W., 1719 N. 18th St., Boise, Ida., Medical Social Worker, Crippled Children's Service, State Dept. of Public Health

Public Health Education Section

Laura H. Berkeley, 2090 Morris Ave., New York, N. Y., Asst. in Health Education, City Dept. of Health

Kathleen S. Boland, 144 Pawling Ave., Troy, N. Y., Health Educator-in-Training, State Health Dept.

Mary E. Chilson, M.P.H., Cabarrus County Health Dept., Concord, N. C., Public Health Educator

Irene H. DeSarmo, M.P.H., P. O. Box 110, Redwood City, Calif., Health Education Consultant, San Mateo County Health Dept.

Peter W. Edwards, M.B., Cheshire Joint Sanatorium, Market Drayton, Salop, England, Medical Supt.

Mabel Foster, 121 Fairview Ave., Stamford, Conn., Nursing Field Representative, American National Red Cross

Edward M. Gunn, M.D., 4105 Warner St., Kensington, Md., Chief, Army Medical Illustration Service, Army Institute of Pathology

Beatrice A. Hruska, R.N., M.P.H., Montana Tuberculosis Association, Helena, Mont., Director of Health Education

Arthur Kneerim, 1 Madison Ave., New York, N. Y., Director, Field Service Bureau, Health and Welfare Division, Metropolitan Life Insurance Co.

Carmen LaFontaine, Box 59, Rio Piedras, P. R., Medical Social Worker, P. R. Health Dept.

Ada Miller, M.J., 411 Equitable Bldg., Baltimore 2, Md., Exec. Secy., Maryland Society for Prevention of Blindness

Adolfo L. Monserrate-Anselmi, Box 322, Rio Piedras, P. R., President and Exec. Director, P. R. Pharmaceutical Assn.

Nancy C. Ott, M.A., International House, Berkeley 4, Calif., Graduate Student in Health Education, School of Public Health, Univ. of California

Mary Pollard, M.P.H., State Health Dept., P. O. Box 711, Santa Fe, N. M., Health Education Consultant

Mefford R. Runyon, 47 Beaver St., New York, N. Y., Exec. Vice-President, American Cancer Society

Eric S. Smith, 5474 Vine St., Vancouver, B. C., Canada, Acting Sanitary Inspector, Dept. of National Health and Welfare

Philip L. Weinstein, M.P.H., P. O. Box 1078, Bellingham, Wash., Health Educator, Bellingham and Whatcom Co. Health Dept.

Public Health Nursing Section

Clarissa E. Barnett, 759 Main St., Leominster, Mass., Nurse in Charge, Leominster Chapter, American Red Cross Nursing Service

Elizabeth P. Bradley, R.N., City Hall Bldg., Lawrence, Kans., Public Health Nurse, Lawrence-Douglas County Health Dept.

Virginia P. Cranshaw, M.P.H., Mary Kirkland Hall, Vanderbilt Univ., Nashville, Tenn., Asst. Professor of Medical Nursing

Germaine A. Emerson, Grandview Apts. 105, Kelso, Wash., Supervisor of Public Health Nurses, Cowlitz-Wahkiakum County Health Dept.

Rafaela Rodena-Garcia, 1958 Eduardo Conde Ave., Santurce, P. R., Public Health Nurse, P. R. Public Health Service

Vera P. Hansel, R.N., M.A., U.S.P.H.S., 239 Federal Office Bldg., San Francisco, Calif., Mental Health Nurse Consultant

Juliette Julien, B.S., 179 2nd St., Troy, N. Y., Director of Nursing, Rensselaer County Health Dept.

Veronica R. Marks, R.N., B.S., 709 Kilmer Press Bldg., Binghamton, N. Y., Acting District Supervising Nurse, State Health Dept.

Helen B. Meister, R.N., B.S., P. O. Box 221, Parsons, Kans., Supervisor of Public Health Nurses, Labette County Health Dept.

Ann Miller, M.N., Tohoku Mil. Govt., APO 309, % Postmaster, San Francisco, Calif., Regional Public Health Nurse

Edith L. Mitchell, R.N., B.S., 2324 Pacific Ave., Tacoma 2, Wash., Supervisor of Nurses, Pierce County Health Dept.

Clara L. Nicholson, R.N., B.S., 1618 23rd Ave., Longview, Wash., Staff Nurse, Cowlitz-Wahkiakum County Health Dept.

Dorothy K. Pollack, R.N., B.S., 5421 Baywood St., Pittsburgh 6, Pa., Student, Univ. of Pittsburgh

Josephine Remley, 123 Columbia Terrace, Peoria, Ill., Nursing Consultant, Division of Services for Crippled Children, City Health Dept.

M. Christine Rennie, C.P.H., 42 Howe St., New Haven, Conn., Student, Yale School of Public Health

Anita L. Schuelke, R.N., B.S., 224 Malone Ave., Peoria, Ill., Director of Nurses, Peoria County Health Dept.

Mary M. Scott, R.N., B.S., 1800 East 21st, Topeka, Kans., Consultant in Maternal and Child Health, State Board of Health

Ruth H. Sprague, R.N., M.P.H., Wayne County Health Dept., Henry Ruff Rd., Eloise, Mich., Orthopedic Nursing Consultant

Inez B. Trelstad, R.N., B.S., 1908 8th Ave., North, Seattle 9, Wash., Chief Nurse,

Regional Office, Veterans Administration

Cecilia E. Walsh, B.S., 136 Whitford Ave., Providence 8, R. I., Director, District Nursing Association of Fall River, Mass.

Alice Westerberg, R.N., B.S., 22 Glenbrook Rd., Stamford, Conn., Director, Port Chester Visiting Nurse Assoc.

Epidemiology Section

Ralph E. Dwork, M.D., M.P.H., 899 Montgomery St., Brooklyn 13, N. Y., Graduate Student, Columbia Univ. School of Public Health

Morris A. Granoff, M.D., 327 Whalley Ave., New Haven 11, Conn., Asst. Epidemiologist, New Haven Health Dept.

Jose A. Hernandez-Matos, M.D., P. O. Box 194, Rio Piedras, P. R., Epidemiologist, Insular Health Dept.

M. Elizabeth Leeds, R.N., B.S., Federal Security Bldg., South, Rm. 5524, Washington, D. C., Research Nurse, Division of Tuberculosis Control, U. S. Public Health Service

L. J. Peters, M.D., 2238 Professor St., Cleveland 13, Ohio, Medical Inspector, Department of Health

Warren Winkelstein, Jr., M.D., Office of Prof. Training & Recruitment, State Health Dept., Albany, N. Y., Apprentice Epidemiologist

School Health Section

Richard R. Abbot, M.S., Western Illinois State College, Macomb, Ill., Health Coordinator

Henry F. Fricker, 540 Lowell Ave., Palo Alto, Calif., Graduate Student in Health Education, Stanford Univ.

Daniel I. McLean, M.D., 5357 9th Ave., Los Angeles 43, Calif., Acting Physician Supervisor, Los Angeles City Schools

Dental Health Section

William H. D'Abbraccio, D.D.S., 613 Chalkstone Ave., Providence, R. I., Dentist

Lloyd F. Richards, D.D.S., P. O. Box 555, Berkeley, Calif., Graduate Student, School of Public Health, Univ. of California

Medical Care Section

Arthur M. Alden, M.D., 1127 Pine St., St. Louis, Mo., Chief of Staff, Labor Health Institute

David F. Burgoon, 2931 South Columbus St., Arlington, Va., Laboratory Specialist, U. S. Public Health Service

Tracy Copp, 624 South Quincy St., Green Bay, Wis., Board Member, Green Bay Curative Workshop

Seymour Etkin, M.A., 2nd & Auburn Ave., Rt. 1, East Riverdale, Md., Economist, Bureau of Census, Dept. of Commerce

Henry G. Farish, M.D., M.H.A., 134 Lewis St., Southampton, N. Y., Administrator, Southampton Hospital Assoc.

Zelma Fluharty, R.N., B.S., Presbyterian Hospital, Denver 6, Colo., Director of Nursing Education and Nursing Service

William Freeman, M.D., 473 June St., Fall River, Mass., Pathologist and Director of Laboratories, Truesdale Hospital

J. F. Friedheim, M.A., Jameson Memorial Hospital, New Castle, Pa., Director

Gwen Goodrich, University of Wisconsin, Madison 5, Wis., Instructor in Schools for Workers

Charles M. Grossman, M.D., University of California, Berkeley, Calif., Research Fellow in Biochemistry

Esther R. Hauptli, R.N., M.A., 534 Walhalla Rd., Columbus, Ohio, Medical Social Work Consultant, Ohio State Dept. of Public Welfare

Charles Hilsenroth, 2423 Dexter Ave., Silver Spring, Md., Hospital Program Analyst, U. S. Public Health Service

George H. Hoxie, M.D., A.M., 2808 Hillegass Ave., Berkeley, Calif., Retired Physician

William A. MacColl, M.D., 201 Securities Bldg., Seattle 1, Wash., Pediatrician, Group Health Cooperative of Puget Sound

Hugh McCulloch, M.D., 6501 S. Promontory Drive, Chicago 49, Ill., *Medical Director*, Council on Rheumatic Fever, Heart Assoc., Chicago

Francis C. MacDonald, M.D., 39 Main St., Concord, Mass., Director, Harvard Pediatric Study

Hugh Montgomery, M.D., Hospital of Univ. of Pennsylvania, Philadelphia 4, Pa., Asst. Professor of Clinical Medicine, Medical School

Dorothy A. Oates, 33 Atlantic Terrace, Lynn, Mass., Supervisor of Physical Restoration, Division of Vocational Rehabilitation, Massachusetts Dept. of Education

James N. O'Brien, M.D., 112 Market St., Harrisburg, Pa., Chief Medical Consultant, Bureau of Rehabilitation, State Board of Vocational Education

John E. Petersen, M.S., Welfare Council, 729 S. Figueroa St., Los Angeles 14, Calif., Director, Health Division

Mortimer S. Rayman, M.D., Two Harbors, Minn., General Practitioner, Community Health Center

Marion Rickert, 11 South Lake Ave., Albany 3, N. Y., Supervisor of Medical Social Work, State Dept. of Social Welfare

Mary Roddy, M.Sc., 616 K. St., Sacramento, Calif., Medical Social Work Consultant, State Dept. of Social Welfare

Aldo S. Romiti, 119 West 117th St., Seattle,

Wash., Exec. Asst., Physical Medicine Rehabilitation Division, Veterans Administration

Sidney C. Selkovits, M.D., 105 Beaver St., Sewickley, Pa., Medical Consultant, Bureau of Rehabilitation, State of Pennsylvania

Theodate H. Soule, M.A., 525 East 68th St., New York 21, N. Y., Director of Social Service, New York Hospital

Louise O. Waagen, 3130 Wisconsin Ave., N.W., Apt. 115, Washingtin 16, D. C., Chief, Nursing Section, Division of Hospital Facilities, U. S. Public Health Service

Douglas N. West, M.S.P.H., 1540 East-West Highway, Silver Spring, Md., Chief, Office of Program Operation, Division of Hospital Facilities, U. S. Public Health Service

Unaffiliated

Louise A. Bailey, 5528 S. Hyde Park Blvd., Chicago, Ill., Consultant in Physical Therapy, National Society for Crippled Children and Adults

Mrs. Z. H. Coberly, China Training Institute, Chiaoton Tseng, Kiangsu, China, Midwifery Teacher, Seventh Day Adventists Mission

Floyd S. Daft, Ph.D., National Institutes of Health, Bethesda 14, Md., Chief, Laboratory of Biochemistry and Nutrition

Richard L. Dills, Box 489, Pasco, Wash., General Sanitarian, Benton-Franklin County Health Dept.

Mildred Erickson, M.S.W., 1209 Burlingame Ave., Rm. 203, Burlingame, Calif., Exec. Secy., Council of Social Agencies of San Mateo County

Dr. B. L. Frank, 1235 McGill College Ave., Montreal, Que., Canada, Medical Director, Ciba Co., Ltd.

Heber R. Harper, Ph.D., 321 Equitable Bldg., Denver 2, Colo., Regional Director, Federal Security Agency

Edwards A. Park, M.D., M.A., Johns Hopkins Hospital, Baltimore 5, Md., Professor Emeritus of Pediatrics, Johns Hopkins Univ.

Eugene J. Pope, D.V.M., P. O. Box 72, Norfolk 1, Va., City Veterinarian

Eloise R. Robins, 803½ East Main St., Richmond 19, Va., Secy., Health Division, Richmond Area Community Council

Adolph S. Rumreich, M.D., Dr.P.H., 381 Marion Ave., Glen Ellyn, Ill., Medical Director, U. S. Public Health Service; Liaison Officer, Fifth Army

James E. Scatterday, D.V.M., P. O. Box 210, Jacksonville, Fla., Public Health Veterinarian, State Board of Health

Anna L. Sweeley, M.A., 1719 N. 18th St., Boise, Ida., Physical Therapy Consultant, Crippled Children's Service, State Dept. of Public Health

Ruth Taylor, Municipal Hospital, Pittsburgh 13, Pa., Hospital Manager, City Dept. of Public Health

Edwin G. Williams, M.D., D.T.M., U. S. Public Health Service, Washington 25, D. C., Chief, Office of Radiological Health

---

ENGINEERING SECTION PROJECT CONTINUED FOR 1949

In 1946, under the impetus of the Engineering Section Council, a special project was established under the title Engineering Section Project. The purpose of the Project, briefly, was to explore ways by which wider use of properly trained engineers and sanitarians could be obtained, and what type of training was desirable for the various types of specialists employed in the environmental sanitation field. The Project had as another goal that of citing administrative techniques, procedures and programs in the field of interest of the Engineering Section. Sufficient funds for a two year project were obtained from the National Foundation for Infantile Paralysis and a group of sanitary engineering manufacturing industries. During 1947 and 1948, the Project has been carried on with enthusiasm under the advice of the Engineering Section Council and a specially formed advisory committee representing the Standing Committees of the Association and the Engineering Section. William T. Ingram has served as the Engineering Field Associate carrying on the Project.

Much has been done in achieving the original goals of the Project, so it is with a great deal of satisfaction that we announce the continuation of the Project through 1949 through

funds generously made available from

The National Sanitation Foundation
The American Can Company
Wallace & Tiernan Co., Inc.

In addition, funds have been made available from the National Security Resources Board for the Preparation, by the Engineering Section Project, of a roster of engineering personnel. Other activities of the Project during 1949 will center around consultation with various universities on course content for engineers and sanitarians; establishment of short courses for the training of water works, sewage plant, and food handling personnel. In addition, a great deal of time will be spent in establishing and supervising a research project in administrative procedures made possible by a grant through the U. S. Public Health Service.

PROGRESS OF THE MERIT SYSTEM SERVICE, A.P.H.A.

As of February 1, 1949, the Merit System Service reports that 523 examinations have been prepared and used by 37 states in the following fields of public health: environmental sanitation, health education, laboratory, medical social work, medicine and public health, nursing and public health nursing, nutrition, and vital statistics.

In addition, 8 cities have used 11 examinations for public health positions and 20 programs of study in public health nursing and 11 visiting nurse associations have used the guidance tests for students and staff nurses. Two schools of engineering have used student tests and a licensing examination for health officers and inspectors has been provided in New Jersey.

Examinations are in preparation in several new areas: pharmacy, veterinary medicine, psychology, hospital nursing positions (consultant level), and dietetics.

New consultants who have joined the staff within the past year are:

Agnes Landis, Ph.D. (Psychology), Clinical Psychologist, Director of Research, Regional Office, Veterans Administration, Brooklyn, N. Y.

Catherine Leamy (Nutrition), Regional Nutrition Consultant, Children's Bureau, New York, N. Y.

Leonora B. Rubinow (Medical Social Work), Newark, N. J.

Alexander Zeissig, D.V.M. (Veterinary Medicine), Veterinary Consultant, Division of Medical Science, New York State Health Department, Albany, N. Y.

There are now approximately 22,800 examination questions in the Merit System files, which have been constructed by 373 writers and reviewed by 559 persons representing the respective professional fields. The writers and reviewers are distributed geographically throughout the country to insure representative opinion and prevent overweighting with urban or eastern interests.

In coöperation with the Public Health Service, the Merit System, during the past two years, has constructed 43 examinations for surgeons, nurses, sanitary engineers, pharmacists, and dietitians in the Division of Commissioned Officers. Promotional examinations for surgeons and nurses are now in the planning stage, as are entrance examinations for veterinarians, dentists, psychologists, and twenty other scientific specialties.

A.P.H.A. membership application blank on page LIII

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

Sanitarian for City-County Health Department. Generalized program. State qualifications and salary expected. Travel allowance 8¢ a mile. Retirement plan, sick leave, vacation. Write: City-County Health Dept., Safety Bldg., Eau Claire, Wisc.

Two Staff Nurses for generalized Public Health Nursing Program adjacent Washington, D. C. Three weeks paid vacation, sick leave, 40 hour week, merit salary increases, opportunity to attend universities part time in Washington. Must own car. Write: Personnel Director, Arlington Court House, Arlington, Va.

Physician Public Health Officer—A limited number of vacancies for Public Health Officers with Military Government in Japan are open. These involve supervision of Japanese Prefecture (State) Health Departments in all phases of public health programs. Excellent opportunity for broad experience in public health under two year contract, renewable if desired. Salary $6,858, free housing for health officer and family plus free transportation to and from Japan. For details and application form write: Chief, Public Health and Welfare Section, GHQ, SCAP, APO 500, % Postmaster, San Francisco, Calif.

Health Officers for positions in State District Offices. Excellent retirement system and Civil Service. Write: Roland R. Cross, M.D., Director, State Department of Public Health, Springfield, Ill.

Dentist—Full-time, to serve as dental clinician in a rural school dental health program. Salary $5,000 per annum. Appointee will operate a modern, well equipped mobile dental unit. Write: S. D. Sturkie, M.D., Director, Joint Health Department, Charlottesville, Va.

Educational Director for voluntary nursing agency, generalized program; undergraduate and graduate students accepted for field experience; interesting opportunity for beginner in educational field. B.S. degree and supervisory experience required. Write: **Box A-51**, Employment Service, A.P.H.A.

Dentist for Children's Operative Clinics in the Cincinnati Schools, half-time, five days per week. Minimum annual salary full-time, $3,954, maximum, $4,754; vacation with pay; sick leave and retirement; license to practise in Ohio necessary. Write: Dr. E. H. Jones, 530 Provident Bank Bldg., Cincinnati, Ohio.

Supervising Public Health Nurse, present salary range $291.75 to $361.75 plus car allowance; automatic increases; cost-of-living salary adjustments semi-annually. Application for examination may be obtained by writing to: Personnel Division, City Hall, Madison 3, Wisc.

Assistant Health Officer. Opportunity for young physician in large county; generalized program with emphasis on tuberculosis control. Previous experience and training desirable but not essential. Salary $7,000 to $7,500 plus car allowance and official expenses. Write: **Box A-52**, Employment Service, A.P.H.A.

Public Health Nurses for a well established, generalized program, including school health, in a partly rural California county with a population of about 65,000. Present salaries: Junior grade, $2,640–$3,216; Senior grade, $2,916–$3,540. Probable general increase soon. Car needed; travel allowance 6¢ per mile; vacation, sick leave, all legal holidays, 38 hour week, merit system being established. Write: Health Officer, Box 360, San Luis Obispo, Calif.

Director of Health Education, in a rural and urban County Health Department adjacent to Washington, D. C. To conduct a broad and general Public Health Program in close integration with voluntary health organizations. Write: Montgomery County Civil Service Commissioner, Old Court House Bldg., Rockville, Md.

Chief Medical Officer: Extensive, diversified, well established medical, public health and sanitation two-government cooperative program in urban and rural

areas in Bolivia, requires licensed physician with graduate training plus a minimum of 5 years' full-time experience in public health work. Age, under 60. Married or single. Total remuneration range $10,518 to $13,761 per annum. Minimum desirable period service 2 years. English speaking colleagues. Transportation provided for employee and dependents. Write: Director, Health and Sanitation Division, Institute of Inter-American Affairs, 499 Pennsylvania Ave., Washington 25, D. C.

Physician as Director City-County Health Department, population 56,000; staff of 14; ideal offices and laboratory. Salary for man with degree in public health $9,000 plus 8¢ per mile travel. Write: City-County Health Department, Safety Bldg., Eau Claire, Wisc.

Tuberculosis Control Director for State Department of Health; salary range $6,480–7,440. Some administrative experience in Tb Control work required, also graduation from an approved school of medicine; one year internship; eligibility for an Arizona license and two years' experience in public health work or graduate study in public health. Write: J. P. Ward, M.D., Director, State Dept. of Health, Phoenix, Ariz.

Public Health Nurse: For generalized program including school service. Staff of 40 nurses. Completion of accredited course in public health nursing required. County car or 7¢ per mile for personal car. Beginning salary $2,940 per annum. Merit system, five day week, good personnel policies.

Physician: Training and experience in Public Health required. County car or 7¢ per mile for personal car. Beginning salary $5,700 per annum, maximum salary $7,140. Merit system, 40 hour week, good personnel policies.

Public Health Laboratory Technician: Opening in a modern, well equipped laboratory requiring professional training and experience. Staff of 12 technicians under direction of M.D. Entrance salary $3,540 per annum. Merit system, 40 hour week, good personnel policies.

Write: (three above positions) Kern County Personnel Department, Rm. 108 Court House, Bakersfield, Calif.

Food Sanitarian for large County Health Department, both rural and urban population of approximately 130,000. Should have B.S. in biological science or chemistry, as well as one year's experience in food sanitation with a full-time local health department. Salary $3,600. Must have car, mileage reimbursed on a sliding scale. Write: Director, Will County Health Department, 21 E. Van Buren St., Joliet, Ill. Include snapshot and short history in first letter.

Public Health Staff Nurses—Beginning salary $2,760 plus $900 maximum travel allowance. Consideration will be given for training and experience. Liberal vacation and sick leave. Ottawa County is located near a large city with many cultural interests and opportunities for advanced education. Population both rural and urban approximately 70,000. Write: Director, Ottawa County Health Department, Court House, Grand Haven, Mich.

Assistant Sanitarian for city and county generalized program with emphasis on food and milk sanitation. Degree, training and experience required. Beginning salary $3,000 or more according to experience plus $900 maximum travel allowance. Retirement plan, sick leave and liberal vacation. Write: Director, Ottawa County Health Department, Court House, Grand Haven, Mich.

Supervising Public Health Nurse for modern generalized nursing program. Minimum requirements, public health certificate or one year of graduate study in public health nursing. Salary range $278 to $318; 40 hour week; retirement plan; sick leave. Write: Charles A. Neafie, M.D., Director, Department of Public Health, Pontiac 15, Mich.

Public Health Nurses for generalized nursing program, salary range $265–$285 per month; 40 hour week; vacation and sick leave; car furnished. Write: Director of Public Health Nursing, 504 County-City Bldg., Seattle 4, Wash.

Public Health Engineer or experienced and well trained Sanitarian to plan and conduct a municipal program in Public Health Sanitation, with emphasis on insect, food and milk control, in city of about 15,000. Prefer resident of southeastern states. Write: Box 146, Hartsville, S. C., Commissioner of Health.

Dentist to operate a mobile dental unit in rural sections. Opening available May 1. Starting salary $4,500 plus liberal travelling allowance. Write Box A-53, Employment Service, A.P.H.A.

Health Educator for Department of Public Health and Preventive Medicine at western medical school. Rank of Instructor or Assistant Professor. M.P.H. or Master's Degree in Public Health Education and at least 5 years' experience required, preferably including teaching experience. Duties will consist mainly of teaching and consultation. Write Box A-54, Employment Service, A.P.H.A.

Announcements

United States Civil Service Commission, Washington, D. C.

Examination for Industrial Hygienist

Applications are now being accepted for an Industrial Hygienist examination which has been announced to fill positions in various field activities of the Navy Department, and in other federal agencies, in Washington, D. C., and throughout the United States. Salaries range from $3,727 to $6,235 a year.

For further information see Announcement No. 4-34-1 (1949) at any first- or second-class post office, where the necessary application forms may also be obtained. Applications will be accepted until further notice, and must be filed with the Executive Secretary, Board of U. S. Civil Service Examiners for Scientific and Technical Personnel of the Potomac River Naval Command, Bldg. 37, Naval Research Laboratory, Washington 25, D. C.

California State Personnel Board

Examinations for Assistant Sanitary Engineer and Associate Sanitary Engineer

The California State Personnel Board announces nation-wide examinations for Assistant Sanitary Engineer and Associate Sanitary Engineer for May 21, 1949. Positions will be available with the Bureau of Sanitary Engineering of the California Department of Public Health. At least two years of sanitary engineering experience and graduation from college in sanitary or public health engineering is required. Salary for the Assistant Sanitary Engineer is $341 to $415 a month; for the Associate Sanitary Engineer, $415 to $505 a month.

Applications for the May examination must be filed on or prior to April 30, 1949. Address inquiries to: Recruitment Section, California State Personnel Board, 107 State Building, San Francisco 2, Calif.

United States Public Health Service

Regular Corps Examination for Medical Officers

A competitive examination for appointment of Medical Officers in the Regular Corps of the U. S. Public Health Service will be held on May 3, 4, and 5, 1949, at various points throughout the United States.

Appointments are permanent in nature and provide opportunities for a lifetime career in clinical medicine, research, and public health at Marine Hospitals and other Public Health Service facilities.

Appointments will be made in the grades of Assistant Surgeon (1st Lt.) and Senior Assistant Surgeon (Captain). Entrance pay for an Assistant Surgeon with dependents is $5,011 a year; for Senior Assistant Surgeon $5,689. Provisions are made for promotions at regular intervals up to and including the grade of Senior Surgeon (Lt. Colonel) and for selection for promotion to the grade of Medical Director (Colonel) at $9,751 per annum. All applicants must be United States citizens of at least 21 years of age, and possess a diploma of graduation from a recognized school of medicine.

Additional information and application forms may be obtained by writing to the: Surgeon General, U. S. Public Health Service, Washington 25, D. C., Division of Commissioned Officers. Completed applications must be received by April 14, 1949.

POSITIONS WANTED

Medical Administrator — experienced county health officer, M.P.H. (Columbia), age 38, wants more responsible position with larger salary, as director county or city unit, or voluntary agency. Previous training and experience in hospitals, private practice, army preventive medicine, industry. Write: **Box C-10,** Employment Service, A.P.H.A.

Health Educator—M.P.H., male, single. 19 years of formal education including half year study of public health in Sweden. Army experience in environmental and personal hygiene, counseling, communicable diseases. Basic teaching and A.P.H.A. field work requirements satisfied. Interested in school and public health education, mental health and alcoholism. Write: **Box HE-11,** Employment Service, A.P.H.A.

Sanitary Engineer, B.S. M.C.E. 35 years; 12 years experience including work in large eastern city health department; Corps of Engineers, Sanitary Corps, U. S. Army; Sanitary Engineer in charge in large federal agency. Design and opera-

tion experience in all phases. Professional Engineering license, New York State. Write: Box E-8, Employment Service, A.P.H.A.

Sanitary Engineer, B.S. in Chemistry; age 30; 5 years field experience in sanitary engineering; 4 years office design experience. Interested in position in public health as sanitary engineer involving responsibility with industry or official agency. Write: Box E-9, Employment Service, A.P.H.A.

Veterinarian, 26, single, M.P.H. (Michigan) advanced work in bacteriology and parasitology; experience in animal disease control, milk and food sanitation, private practice. Interested in position in official agency, industry or laboratory in the United States or overseas. Write Box V-7, Employment Service, A.P.H.A.

Industrial Hygienist, M.S. in industrial hygiene expected in May including training in engineering and laboratory technics and occupational disease aspects of industrial hygiene. Experience (one year) in environmental sanitation program in metropolitan health department. Write Box I-H-2, Employment Service, A.P.H.A.

Bacteriologist—Ph.D. (June, 1949). Interested in academic, industrial, or public health opening preferably in the Northeast. Three years research on quaternary ammonium germicides. Age 28, married, veteran. Write: Box LD-3, Employment Service, A.P.H.A.

Dentist, male, 30 years old, M.P.H. expected in June; 5 years experience clinical and public health experience (civilian and in U. S. Army). Interested in administrative or part-time clinical opening in U. S. or overseas. Write: Box D-4, Employment Service, A.P.H.A.

Annual Service Plan for Public Health Examinations

A quarter of the states of the Union are now members of the Annual Service Plan of the Merit System Service and the first county (Nassau County, New York) joined in March. The states are: Colorado, Idaho, Illinois, Kentucky, Maine, Maryland, Mississippi, New Hampshire, New Jersey, North Dakota, Oklahoma, and Vermont.

Under this plan, which was initiated in 1948 and has been approved by the Public Health Service, the Children's Bureau, and the Executive Board of the Association, and has been heartily endorsed by the Association of State and Territorial Health Officers, an unlimited number of standard examinations are provided to an agency at an annual service fee including all positions for which the Merit System Service has such examinations available. New subject-matter areas are constantly being added as need arises. Other benefits in terms of aids in personnel administration go to members of the plan, and it is expected that many of the 37 states which have already used the Service will join the plan by July 1.

Information regarding the benefits of joining the plan and the cost may be secured from the Merit System Service.

The plan is also open to municipal and county civil service agencies.

All communications should be sent to Burneice Larson, Medical Bureau, Palmolive Building, Chicago 11, Ill.

Opportunities Available

WANTED—(a) Public health physician to direct well established program, South American country; English speaking colleagues; $10,000–$13,000, transportation for self, dependents. (b) Dentist experienced in public health dentistry; regional consultant position; South. (c) Public health physician to direct division of geriatrics and adult hygiene; metropolitan health department. (d) Professor of preventive medicine; should be qualified to teach preventive medicine and public health with a primary emphasis on preventive medical aspects; East. (e) Woman physician to direct student health program; approximately 1,000 women students and faculty members; $5,000, maintenance. (f) Director, maternal and child health and crippled children's services; state health department; West. (g) Student health physician; liberal arts college; California. (h) Director, city-county health department; staff of fourteen; town of 45,000; Middle West. PH4-1 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

WANTED—(a) Coördinator of training; state health department; Master's desirable; $5,000. (b) Sanitary engineers, public health engineers, and specialists in fields of malaria and insect control; positions of considerable responsibility; South America. (c) Health educator; state division of national organization; New England. (d) Sanitary chemist; qualified to conduct lake pollution investigation; laboratories of state university; Middle West. (e) Public health engineer; state department; Middle West. (f) Health educator to join faculty, university department of health; rank: instructorship ($4,200–$5,000) or assistant professor ($4,800–$5,600). PH4-2 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

WANTED—(a) Director; newly established visiting nurse association; vicinity New York City; $4,000. (b) Director of public health nursing; state department; headquarters in college town; West; $4,800. (c) Educational director; visiting nurse service; South. (d) Assistant professor of public health nursing; eastern university. (e) Maternal and child health nursing consultant; West; $4,000. (f) Supervisors and staff nurses; newly established city-county health department; Middle West. (g) Supervisor; generalized program, including tuberculosis division, school program; university town, California. (h) Supervisor; nursing staff, municipal health department, Chicago area; $4,500. (i) Supervisor of nurses; public school system; 16,000 children; staff of fourteen nurses; Middle West. PH4-3 Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Opportunities Wanted

Public health physician; Master's in Public Health, eight years, administrative health officer, principally in rural areas; five years, director, metropolitan health department; for further information please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Public health dentist; D.D.S., M.S.D. (Children's Dentistry), M.P.H. (Public Health); several years, teaching experience; for further information please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Sanitary engineer; M.S. (Sanitary Engineering); eleven years, Division of Industrial Health, state department of health, five years as assistant director and six as director; for further information please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Health Educator; M.P.H., Harvard; four years, statistician; eight years, health educator, state health department; for further information please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Public health nurse; B.S. (Public Health Nursing); four years, school nurse; seven years, supervisor, metropolitan health department; for further information please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

THE AMERICAN BOARD OF PREVENTIVE MEDICINE AND PUBLIC HEALTH, INC.
DIGEST OF REQUIREMENTS FOR CERTIFICATION OF PHYSICIANS

As previously announced in the *American Journal of Public Health* (March, 1949, p. 426), the American Board of Preventive Medicine and Public Health, Inc., has been set up, with representation from the American Medical Association, the American Public Health Association, the Canadian Public Health Association, the Southern Medical Association, and the Association of Schools of Public Health.

The Board was created in accordance with action of the Advisory Board for Medical Specialties and was approved by the Council on Medical Education and Hospitals of the American Medical Association in February, 1949. The principal purposes of the Board as defined in the articles of incorporation are:

1. To encourage the study, improve the practice, elevate the standards, and advance the cause of preventive medicine and public health.
2. To grant and issue to physicians duly licensed by law to practise medicine Certificates of special knowledge in preventive medicine and public health.

Requirements for Certification

General Qualifications

1. Moral and ethical standing in the profession satisfactory to the Board.
2. Graduation from a medical school in the United States or Canada approved by the Council on Medical Education and Hospitals of the American Medical Association, or from a foreign medical school satisfactory to the Board.
3. An interneship of at least one year in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or in a foreign hospital satisfactory to the Board.
4. Licensure to practise medicine in the United States or the Dominion of Canada.
5. Special training in preventive medicine or public health which shall include:
   A. A period after interneship of not less than six years of special training, teaching, or practice in preventive medicine and public health which must include B and C.
   B. Successful completion of at least one academic year of graduate study leading to the degree of Master of Public Health, or an equivalent degree or diploma, or an equivalent satisfactory to the Board.
   C. Field training or residency of at least two years of field experience in general public health practice, which included planned instruction, observation and active participation in a comprehensive, organized, public health program, one year of which may be an approved clinical residency in a field directly related to public health.
6. Limitation of practice to teaching or practice of preventive medicine or public health as a specialty.

The Founders Group

The By-Laws authorize the Board for a period of time ending July 1, 1950, to excuse from examination practitioners of preventive medicine or public health who have attained unquestioned eminence in the field.

Examinations

Examinations will be held from time to time and in various places depending upon need as indicated by applications received. It is expected that examinations will be held primarily in connection with the meetings of the American Public Health Association. The examination will consist of two parts:

Part one to consist of a comprehensive written examination designed to test the knowledge of the applicant in the general field of preventive medicine and public health. These examinations will

be announced at least sixty days prior to the holding of the examinations. The written examination will be confined to one day. Part two to consist of the oral or practical examination which will be held on the day following the written examination. This examination will be held before two to four examiners, members of the Board or associate examiners. An endeavor will be made to adapt the details of the oral examination to each candidate's experience and practice. The examiners will report orally upon each candidate to the assembled Board, after which the results of the examination will be considered jointly by the entire Board and the examiners. Final action of the Board will be based upon the candidate's ethical and professional record, training, and attainments as well as on the results of his formal examination.

Applications

Applications which must be on prescribed application forms are to be filed with the Secretary not less than 90 days prior to the date of examination.

Fees

The Board is incorporated as a nonprofit corporation and no member of the Board may receive any compensation. Minimum fees are specified, consistent with the cost of examination and certification. The total cost to the applicant is $50.00.

Application fee $15.00

No application can be considered for classification and action by the eligibility committee unless accompanied by the application fee. The application fee is not refundable.

Certification fee $35.00

This fee is payable when the candidate is notified of acceptance for examination or as a member of the Founder's Group. It is not returnable after the candidate has been officially accepted and notified by the eligibility committee to report for examination.

Certification

Upon satisfactory completion of the examinations or, in the case of the Founder's Group, upon the affirmative vote of the Board, a certificate will be issued to the effect that the person named has been found to be possessed of special knowledge in preventive medicine and public health. This certificate will be signed by the officers of the Board and shall have its seal affixed. Each certificate shall remain the property of the corporation, but each person to whom a certificate is issued shall be entitled to its possession until revoked. Any certificate issued by the Board may be revoked if evidence, satisfactory to the Board, is presented that the applicant was not eligible at the time of application, or made any missstatement or misrepresentation of facts or that his license to practise medicine has been suspended or revoked.

Persons desiring further information should communicate with the Secretary of the Board, Dr. Ernest L. Stebbins, 615 N. Wolfe Street, Baltimore, Md.

NOTE: Applications to be considered by the American Board of Preventive Medicine and Public Health close 90 days before the announced dates of the examination instead of 60 days as stated in the news item, page 426, *A.J.P.H.*, March, 1949.

AMA OFFERS A PUBLIC HEALTH PLAN

The American Medical Association in mid-February announced a 12 point program for the advancement of medicine and public health. In summary the points are:

1. A federal department of health of cabinet status with a physician as secretary, and coördination in this department of all federal health activities except those of the armed forces.
2. Promotion of medical research through a national science foundation with research grants to private agencies having suitable staffs and facilities.
3. Further development of voluntary hospital and medical care plans, particularly in rural areas, with state aid for including the medically indigent in such programs.

4. A state medical care authority in each state, with proper medical and consumer representation, to receive and administer funds.

5. Acceleration of development of facilities in rural areas under the Hospital Construction Act.

6. Establishment of local public health units to provide communicable disease control, vital statistics, environmental sanitation, venereal disease control, maternal and child hygiene, and public health laboratory services. Salaries to health officials commensurate with their responsibility.

7. Development of a mental hygiene program.

8. Development of health education programs through suitable state and local agencies.

9. Provision of facilities for care and rehabilitation of the aged and those with chronic diseases and other groups not presently cared for.

10. Integration of veterans' medical care with other medical care programs.

11. Greater emphasis on industrial medicine and increased safeguards against highway, home, and farm accidents.

12. Adequate support, without political interference, of medical, dental, nursing and other institutions training necessary specialized personnel for the provision and distribution of medical care.

WHO STRUCTURE

Since the World Health Organization was established as a specialized agency of the UN on September 1, 1948, its structure has been developed, and up to January, 1949, a secretariat of 255 persons were selected. Of these, 194 are in the headquarters office in Geneva, 29 in the New York Office, and 32 in the field.

The Special Assistant to the Director-General, Dr. Brock Chisholm, is Dr. W. Forrest of the United Kingdom. Dr. R. Gautier of Switzerland and Dr. N. Goodman of the United Kingdom respectively are directors of the two main departments of the headquarters office, the department of technical services, and the department of operations. The director of the division of epidemiology in the department of technical services is Dr. Y. Biraud of France.

The director of the South-East Asia regional office in Delhi is Dr. C. Mani of India. The epidemiological intelligence station in Singapore is directed by Dr. P. M. Kaul, also of India. The liaison office in New York is directed by Dr. Frank Calderone of the United States with the assistance of Dr. I. C. Fang of China.

INTERSTATE COÖPERATION IN MEDICAL EDUCATION

The presidential address of Florence Sabin, M.D., at the 1948 meeting of the Western Branch, A.P.H.A., included a reference to the possibility of interstate coöperation by the 8 Rocky Mountain and Inter-mountain States in medical and public health education. (See *A.J.P.H.*, Nov., 1948, p. 1510.)

In further exploration of such a plan there was held in Denver in December, 1948, at the invitation of the governors of Colorado, New Mexico, Utah, and Wyoming, a Mountain States Governors' Conference on Education for Health Services. In the eight Rocky Mountain and Inter-mountain states there are only two medical schools, one in Denver and the other in Salt Lake City; there is only one veterinary school, at Fort Collins, Colo., and no dental school whatever. The Conference met to consider whether under the American system of government states may find a way to coöperate in solving such a problem.

The professional schools already established are finding it difficult to procure adequate support for such expensive forms of education based on the relatively sparse populations of the western states. The states without professional schools find it hard to place their students because the cost of such education is far beyond the tuition charged. For example, medical education costs about $3,000 per student per year.

State constitutions do not permit the allotting of funds for an institution in another state. Therefore, Dr. Ward

Darley, Director of the University of Colorado Medical Center, offered for discussion a plan whereby states without professional schools might grant to their own universities funds to be used by them to pay the full cost of medical education (in the widest sense) for their own students, selected by them with the advice of a member of the admissions committee of a university maintaining a professional school.

The legal implications of this proposal are now being explored as well as the further point as to whether it is necessary to secure a federal enabling act.

NEW MEN ON MEDICAL AID TO CHINA BOARD

Ten new members were recently elected to the 70 man board of directors of the American Bureau for Medical Aid to China. They are Drs.:

Ira V. Hiscock, Chairman, Yale University Department of Public Health
P. Z. King, Chief Medical Advisor, United Nations' International Children's Emergency Fund and former Chinese Vice Minister of Health
H. Dabney Kerr, head, Department of Radiology, University of Iowa, former roentgenologist, Peking Union Medical College
John McK. Mitchell, Dean, University of Pennsylvania Medical School, Executive Officer, 20th General Hospital, Assam, in World War II
J. Howard Mueller, Professor of Bacteriology and Immunology, Harvard Medical School
Wade W. Oliver, Associate Director, Medical Sciences, Rockefeller Foundation
Walter S. Root, Professor of Physiology, College of Physicians and Surgeons, Columbia University
Douglas H. Sprunt, University of Tennessee Institute of Pathology
Ernest L. Stebbins, Director, Johns Hopkins School of Hygiene and Public Health
A. A. Weech, Medical Director, Children's Hospital, Cincinnati, former head, Pediatrics, Peking Union Medical College

FIRST HILL BURTON HEALTH CENTER

The first of 63 public health centers in the United States approved to date for federal aid under the national hospital program was dedicated and opened to the public in Birmingham, Ala., January 27. The building will house offices of the Jefferson County Board of Health, Alabama state laboratories and voluntary agencies, such as the local branches of the tuberculosis association, the American Cancer Society, the National Foundation for Infantile Paralysis, and Visiting Nurses Association.

ARCTIC HEALTH INSTITUTE PROPOSED FOR ALASKA

A resolution was recently introduced into the U. S. Congress requesting a $7,775,000 appropriation for construction in Alaska of an Arctic Health Institute to be located in connection with the University of Alaska at Fairbanks.

The proposed institute is designed for research in all phases of medicine and biology relating to maintenance of health in Arctic and Sub-Arctic Regions. Such problems as the adaptation of housing design and materials for economical use in areas of prolonged low temperature, the development of effective and practical methods for providing safe water supplies at sub-zero temperatures, and methods of safe disposal of human wastes in permafrost areas where ground is permanently frozen during the greater part of the year will be included.

According to the announcement of the Alaska Department of Health, the program of research in Arctic health problems is now under way under the auspices of the recently established U. S. Public Health Service Field Station at Anchorage where studies are planned in the fields of physiology, bacteriology, nutrition, sanitation, and animal diseases.

FELLOWSHIPS IN COMMUNITY NUTRITION

The College of Home Economics of

the University of Tennessee offers several graduate fellowships in Community Nutrition, covering tuition and a stipend of $1,200 for a 12 month period. The program trains candidates for positions as nutritionists with health and welfare agencies and leads to the degree of Master of Science in Community Nutrition. Three quarters of work in residence at the university and one quarter of supervised field work in a health agency are required.

Candidates must have a baccalaureate degree in home economics with a major in foods and nutrition, or its equivalent, and 2 years of experience in teaching, extension work, Farmers Home Agency work, hospital or other food service, or equivalent. Interests and ability of the candidate are further considerations in accepting students for training.

Application blanks and further information may be obtained from the College of Home Economics, the University of Tennessee, Knoxville.

AGE AND DIET

The National Dairy Council has made available reprints of two articles dealing with nutrition as it affects later life. Reprinted from the *Journal of the American Dietetic Association,* they are: Nutritional Status of Older Women, and Dietary Practices of 100 Women 40 to 75 Years of Age. They are the reports of a research project carried on at Michigan State College with the support of the National Dairy Council.

These reprints are available from the National Dairy Council, 111 North Canal St., Chicago 6.

FEDERAL HEALTH GRANTS, CANADA AND THE UNITED STATES

The Canadian National Government appropriates about twice as much for local health services as the United States Government. This is the conclusion of an article, illustrated with pictographs, in the September issue of *Canada's Health & Welfare.*

Of 8 separate areas of health, for only 3 are the Canadian per capita federal grants to provinces less than the United States grants to states—venereal disease, crippled children, and public health research. In all others including general public health, the per capita grants are from 2 to 16 times as large. The greatest discrepancy is in mental health activities where the United States grants to states average 2 cents per capita, those of Canada to the provinces 32 cents.

NATIONAL ADVISORY HEALTH COUNCIL

The current members of the National Advisory Health Council, an advisory body to the U. S. Public Health Service, are as follows:

Term expiring 1949

Ernest E. Irons, M.D., Professor of Medicine, University of Illinois Medical School
William C. Rose, Ph.D., Professor of Chemistry, University of Illinois

Term expiring 1950

Edwin B. Fred, Ph.D., President, University of Wisconsin
Karl F. Meyer, M.D., Director, Hooper Foundation for Medical Research, University of California, San Francisco

Term expiring 1951

George Baehr, M.D., President, Medical Board, Mt. Sinai Hospital, New York
Francis G. Blake, M.D., Sterling Professor of Medicine, Yale Medical School

Term expiring 1952

Reuben G. Gustavson, Ph.D., President, University of Nebraska
Hugh Morgan, M.D., Professor of Medicine, Vanderbilt University

Term expiring 1954

Wilton L. Halverson, M.D., Director, California State Department of Public Health
Thorndike Saville, D.Eng., Dean, College of Engineering, New York University

The four ex-officio members are:

Captain W. Babione (M.C.), U.S.N., Director, Preventive Medicine Division, Navy Department
Assistant Surgeon General R. E. Dyer,

Director, National Institutes of Health
Col. Don Longfellow, M.C., U.S.A., Chief, Preventive Medicine Division, Department of the Army
Harry W. Schoening, Assistant Chief, Bureau of Animal Industry, U. S. Department of Agriculture

LABORATORY IN GROUP DEVELOPMENT

The National Training Laboratory in Group Development will hold its third summer session at Gould Academy, Bethel, Me., June 19–July 8, 1949. The Laboratory is sponsored by the Division of Adult Education Services of the National Education Association and the Research Center for Group Dynamics of the University of Michigan, and with the coöperation of certain other universities. The Laboratory provides opportunity for action leaders, trainers, educators, and social scientists to explore, in a laboratory situation, basic concepts and skills of group growth and group leadership and membership. Further information from Leland P. Bradford, Director, Division of Adult Education Services, NEA, 1201 Sixteenth Street, N.W., Washington 6, D. C.

CLAIR E. TURNER TO IRAN

Clair E. Turner, Dr.P.H., Assistant to the President of the National Foundation for Infantile Paralysis, with a group of specialists in other fields, is making a Public Health Survey in Iran. These experts were sent to Iran by Overseas Consultants under a contract with the Iranian Government.

LEBANON'S FIRST PUBLIC HEALTH EXHIBIT

The American University in Beirut recently initiated an annual Health Week in Lebanon. One of its features was the first public health exhibit ever seen in Lebanon. The exhibit consisted of 40 large panels showing the way disease germs are transmitted. The exhibit was based on the vital need for an enlarged program of public education about the ways through which a healthy body becomes diseased. This need was reported after a sanitary survey of conditions made by a graduate of the University Medical School, Dr. Zeken Shakhashiri, who is now studying at the Johns Hopkins Medical School.

Another aspect of the growing interest in public health was the recent organization of the Lebanese Public Health Association.

CANCER FILM TEACHING "PACKAGE"

A motion picture teaching film, "Cancer: The Problem of Early Diagnosis," is the first in a series of six planned for the next two years for professional audiences. Produced by Audio Productions under the joint sponsorship of the American Cancer Society and the National Cancer Institute, it emphasizes the importance that early suspicion, accurate diagnosis, and effective treatment hold in cancer control.

Prints for single showings may be had from state cancer society officers and state health departments. The film may be purchased for $150 from Audio Productions Inc., 630 Ninth Avenue, New York 19.

BIBLIOGRAPHY ON PLUMBING AND PUBLIC HEALTH

The U. S. Public Health Service has recently made available a revised bibliography on, *Plumbing and Public Health*. It includes items up to July 1, 1948 and replaces the previous bibliography published in 1940. Copies may be obtained from the U. S. Public Health Service, Division of Sanitation, Washington, D. C.

A.M.A. RURAL HEALTH CONFERENCE

The 4th annual rural health conference of the American Medical Association in Chicago on February 4 and 5 was attended by nearly 500 persons, representing farm organizations, state

and federal extension services, agricultural colleges, and allied health agencies. Papers and round table discussions were related to five sections—coöperative health programs for rural areas, environmental hazards, health education, individual and community responsibility, the general practitioner in rural practice, and nutrition and the soil.

The first section recommended that the National Conference on Rural Health go on record as urging that every local area establish a voluntary overall coördinating health agency such as a health council or health committee.

It further recommended complete coverage of the nation with full-time local health units in the belief that this is fundamental to the effective functioning of all health programs.

One of the primary objectives of a health council may well be the attainment of local health units where they do not exist and the strengthening of existing ones.

This section was in agreement with the present efforts of state and territorial health officers, the National Congress of Parents and Teachers, and many other national organizations in supporting, in principle, legislation designed to attain the objectives of full-time local health units coverage for the nation.

The entire Conference adopted an 11 point program of coördination and utilization of existing lay and professional facilities through the following media:

"(1) State and public health services for general community hygiene and communicable disease control; public health nursing, well-baby conferences and clinics.

"(2) The Hill-Burton Hospital Construction Act operating where a community desires such facilities.

"(3) Medical scholarships provided by medical associations, farm bureaus and through legislative appropriations for medical and nursing education to candidates agreeing to practice in rural areas.

"(4) Agricultural school extension services for health education.

"(5) Parent-teacher associations where they encourage school children examinations for hearing, sight, heart, hernia, immunization, school hygiene, as well as physical education.

"(6) Special health groups such as tuberculosis, polio, cancer, heart.

"(7) The application of voluntary prepaid medical and hospital care plans to rural communities.

"(8) Promotion of state and county health councils, the medical profession acting cooperatively with other groups for health education and health activities of local character.

"(9) A plan to bring the medically indigent, or low income, farmer into voluntary prepaid medical plans, which may involve state financial aid.

"(10) Use of the health education programs of farm groups.

"(11) Encouragement of the civilian population, as distinguished from governmental official action, to help itself."

MINNESOTA NUTRITION COUNCIL SEEKS TO CONTINUE FLOUR ENRICHMENT

The Minnesota State Nutrition Council is actively supporting the passage of a bill in the State Legislature to require the enrichment of flour and bread sold within the state in accordance with the standards established by the Federal War Emergency Legislation. Mrs. F. N. Christofferson is Co-Chairman of the Legislative Committee of the Minnesota State Nutrition Council, St. Paul, and Mrs. Helen E. Hughes is Corresponding Secretary.

The American Public Health Association's Governing Council declared October 4, 1944 (*A.J.P.H.*, Dec. 1944, page 1298) that the enrichment of staple food stuffs during the war through federal, state, and voluntary action has resulted in an improvement in the national dietary with respect to several highly essential nutrient elements. The Governing Council pointed out that this enrichment in staple low cost foods has been of proportionately greater benefit to the economic groups whose diet is most in need of betterment.

The Association formally went on rec-

ord as favoring appropriate state and federal action to perpetuate the benefits that have accrued to the national dietary through enrichment of staple foods in accordance with the recommendations of the National Research Council.

ROYAL SANITARY INSTITUTE ISSUES YEAR BOOK

The 1949 *Year Book of The Royal Sanitary Institute,* London, consists of a list of Honorary Fellows, Fellows, members, and associates. A summary follows with a comparative column for the American Public Health Association:

Royal Sanitary Institute	
Honorary Fellows	23
Fellows	642
Members	4,175
Associates	3,174
Total	8,014

American Public Health Association	
Honorary Fellows	22
Fellows	2,093
Members	8,987
Total	11,102

ARGENTINE GROUP ELECTS OFFICERS

The Sociedad Argentina de Patología Infecciosa y Epidemiología of Buenos Aires has announced that the following officers will serve during 1949:

President—Dr. Humberto R. Rugiero
Vice-President—Dr. Lucio A. Garcia
Secretary—Dr. Enrique Callegari
Executive Secretary—Dr. Teodoro Somaloma
Treasurer—Dr. Alfredo Igobone

MISSOURI RIVER BASIN HEALTH COUNCIL ORGANIZED

On July 15, 1948, the health officers of the 10 states in the Missouri River Basin: Colorado, Iowa, Kansas, Minnesota, Missouri, Montana, Nebraska, North Dakota, South Dakota and Wyoming, signed "The Missouri River Basin Sanitation Agreement." Under the agreement, a permanent Missouri River Basin Health Council composed of the health officer and sanitary engineer of each of the respective states was formed.

The following officers were elected:

Chairman—W. S. Petty, M.D., Nebraska State Health Officer
Vice Chairman—J. L. Williams, Jr., M.D., Missouri Acting State Health Officer
Secretary—W. W. Towne, Director, Division of Sanitary Engineering, South Dakota Board of Health

The purpose of the Council has been stated as: ". . . to coöperate with the U. S. Public Health Service and other agencies involved in carrying out a policy for the protection and improvement of the water of this Basin wherever necessary in these states, and the prevention or correction of undue pollution thereof, and in the promotion of specific health programs relative thereto, to the end that full development of the said Basin with its many benefits may be realized by all the people residing in the area."

One of the first committees appointed was the Engineering Committee, composed of the sanitary engineering directors of the 10 states. At a meeting of this committee on December 3 and 4, subcommittees were appointed to study the following subjects:

1. Water standards and classifications
2. Uniform legislation, compacts, etc.
3. Uniform standards for submission of plans, methods and reporting of data, and mapping
4. The scope of environmental sanitation problems in the basin and recommendations for further committee action.

INCREASED HOSPITAL SERVICE RATES

Increased rates effective May, 1949, have been announced by the Associated Hospital Service of New York. This is the second increase in rates during the 14 years of the organization's existence, the first having been in May, 1947. The new rates represent approximately 27 per cent increase over the

previous ones and about 80 per cent over the original ones established in 1935. In the 2 years since the first increase in subscription rates hospital costs are estimated to have increased by 35 per cent.

PILOT MENTAL HEALTH PROJECT

The Division of Mental Hygiene of the U. S. Public Health Service, in coöperation with the Arizona State Department of Health, has established a pilot project in Phoenix, Ariz., designed to develop and strengthen community resources for mental health. Personnel will help mental health training, and consultation staffs of well baby and prenatal clinics, nursery and elementary schools, and health and welfare agencies deal with emotionally disturbed persons in such a way as to obviate the need for psychiatric treatment. The U. S. Public Health Service has assigned Walter M. White, Jr., M.D., psychiatrist, a clinical psychologist, two psychiatric social workers, and one mental health nurse to this project.

HEALTH IN RETARDED AREAS AID PLAN

The blueprints for help to economically backward areas of the world as outlined recently by President Truman stress the integration of the special technical missions that will be sent to various parts of the world. Thus agricultural plans will be supplemented by transportation plans, health programs by educational and agricultural, etc., around the circle of interrelated factors in raising the levels of production and standards of living in underdeveloped regions.

In such a plan, for example, plans for the reduction of infant mortality would go hand in hand with nutrition and food programs, so that there would not be the spectacle of saving babies to die of starvation as children or adolescents. Malaria would be controlled not only as an end in itself, but to produce sufficiently energetic workers to contribute their share to the national economy.

MASSACHUSETTS HEALTH CONFERENCE

The first annual Massachusetts Health Conference was held in Boston on February 19 and 20, under the chairmanship of Philip Mather, President of the National Health Council and of the American Social Hygiene Association. The program included 20 panel sessions on as many health subjects. Among these with their chairmen were:

Medical Care Costs and Methods—Hugh R. Leavell, M.D.

Local Health Units and Health Centers—Robert E. Archibald, M.D.

Citizen Participation in Planning for Health—Margaret Tracy

Rural Health Problems—Jesse Buffum

The Massachusetts Health Conference is made up of some 80 members representing every variety of citizen and professional interest in health in Massachusetts.

REGIONAL CONFERENCES ON LOCAL HEALTH UNITS IN GREAT PLAINS AREA

The National Advisory Committee on Local Health Units of the National Health Council has planned the 3rd and 4th in a series of regional conferences on local health units. The two conferences currently planned are one in Kansas City, Mo., April 20–21, to include Arkansas, Kansas, Louisiana, Missouri, and Oklahoma; and a second in Omaha, Nebraska, April 25–27, to include Iowa, Minnesota, Nebraska, North Dakota, and South Dakota.

The conferences will feature group discussions and group decisions as in the case of the two earlier conferences in Mitchell, Ind., and Salt Lake City. State teams of 10 to 15 persons, representing a cross-section of lay and professional interest in the development of more adequate local health services, will be selected by the respective state health officers.

Resource persons for the conferences will be furnished by such national agencies as the American Heart Association and the American Public Health Association, in addition to the National Health Council.

FIRE DESTROYS CHILE MEDICAL SCHOOL

Fire recently virutally destroyed the School of Medicine of the University of Chile. About 40 per cent of the library of 50,000 volumes was saved. It had just been reorganized by Edward Heiliger of the Rockefeller Foundation after 2 years' work. The journals published before 1940 and 40 per cent of those published after 1939 were saved. The extensive bibliographic material in the Institute of Biology and in the Institute of Microbiology was destroyed. The U. S. Army Medical Library is planning to supply from duplicate stocks some of the books and journals needed in the reconstruction of the Chilean collections. The American Public Health Association is sending to Dr. Hernan Romero, Director of the Laboratory of Preventive Medicine, several recent volumes of the *Journal* to restore that portion of the library. Friends of Dr. Romero who can send other journals and modern books may address them to him at the School of Public Health, University of Chile, Santa Lucia 382, Santiago.

MICHIGAN COMMUNITY CONFERENCE

The University of Michigan School of Public Health Conference on Community Health Services in Ann Arbor, January 31 and February 1, was the 30th in a series of inservice training courses held at the school within the past several years. Its nearly 100 participants were about equally divided between representatives of lay agencies and professional workers in nonofficial and official health agencies, particularly local health officers. It was designed to secure the support of an informed public for better local health units, for complete state coverage, and for a substantial state subsidy of two to three million dollars.

Out of the conference grew the beginnings of a state health committee or council. Its temporary chairman is Charles Leonard, Mayor of Hastings.

The out-of-state speakers included Florence R. Sabin, M.D., Director of Health and Welfare of Denver and Roscoe P. Kandle, Field Director of the American Public Health Association. The consumer viewpoint was presented by Mrs. E. L. Church, President of the Michigan Congress of Parents and Teachers.

CHRONIC ILLNESS COMMISSION ANNOUNCES ITS PROGRAM

As an outgrowth of the Section on Chronic Disease of the National Health Assembly held in Washington in May, 1948, a Commission on Chronic Illness is being set up as a joint project of the American Hospital Association, American Medical Association, American Public Health Association, and the American Public Welfare Association. An Interim Commission is now in operation made up of representatives of the four agencies, looking toward the formation of the permanent Commission in the near future.

The Chairman of the Interim Commission is James R. Miller, M.D., of Hartford, Conn., a member of the Board of Trustees of the A.M.A., which is also represented by Thomas A. McGoldrick, M.D., of Brooklyn, N. Y. The representatives of the American Public Health Association on the Commission are Dean W. Roberts, M.D., M.P.H., Chief of the Bureau of Medical Service, Maryland State Department of Health, Baltimore, and Edward S. Rogers, M.D., M.P.H., Dean of the School of Public Health, University of California, Berkeley.

Albert Snoke, M.D., of New Haven, Conn., and J. Douglas Colman of Baltimore, Md., represent the A.H.A., and

Ellen C. Potter, M.D., of Trenton, N. J., and Judge Thomas S. J. Waxter of Baltimore, represent the A.P.W.A. Mrs. Lucille M. Smith of the Division of Public Health Methods, U.S.P.H.S., Washington, D. C., has been detailed by the Federal Security Agency to assist the Interim Commission as Executive Secretary in establishing the permanent Commission, which will include representatives of the general public, industry, labor, agriculture, education, religion, the social sciences, journalism, and health and welfare.

The program of the Commission goes back to the joint report of the same four agencies on chronic illness (*A.J.P.H.*, October, 1947, pp. 1256–1266). It reflects the considered opinion of these agencies that the patient with chronic illness is one of the major challenges to modern society. Sooner or later some form of long-term illness affects one or more members in most families of the nation. A conservative estimate suggests that more than one-sixth of the population is afflicted with some chronic disease.

The Interim Commission has suggested the following objectives for the permanent Commission:

1. To modify the attitude of society that chronic illness is hopeless; to substitute for the prevailing over-concentration on provision of institutional care a dynamic program designed to prevent chronic illness, to minimize its disabling effects, and to restore its victims to a socially useful and economically productive place in the community.

2. To clarify the problems arising from chronic illness among all age groups, with full realization of its social as well as its medical aspects.

3. To coördinate separate programs for specific diseases with a general program designed to meet more effectively needs which are common to all the chronically ill regardless of the cause or causes of their illness.

4. To clarify the interrelationship of professional groups and agencies now working in the field.

5. To stimulate in every state and locality a well rounded program for the prevention and control of chronic diseases and for the care and rehabilitation of the chronically ill.

Proposed activities of the permanent Commission include:

1. Assembling existing data in order to evaluate and make use of all that is now available and to determine areas requiring further study.

2. Serving as a clearing house for information on laws, programs, experiments, and new developments; to keep all interested groups informed through a newsletter published regularly; and to publish special reports from time to time.

3. Stimulating the development of new methods and techniques in the organization and administration of services for the chronically ill.

4. Developing suggested patterns for integrated community programs.

5. Establishing criteria for the appraisal of state and local chronic disease programs and facilities.

6. Advising private and public state, regional, and local agencies interested in planning for the chronically ill.

7. Suggesting priorities for the determination of immediate as against long-range needs for the guidance of state and local communities.

8. Exploring methods of implementing the recommendations made by the Commission.

9. Preparing a report to the American people outlining a comprehensive plan for the prevention and control of chronic disease and for the care of rehabilitation of the chronically ill.

WHO TO ADMINISTER TWO PRIZES

The World Health Organization will henceforth administer two international prizes in public health. One is the Léon Bernard International Prize for practical results obtained in social medicine, established in 1937 in honor of Professor Léon Bernard, a member of the Health Committee of the League of Nations. The recipient will be selected by the Expert Committee on Social Medicine still to be appointed by the Health Assembly.

It will also administer the Darling Foundation International Malariology Prize to an author of an original study on the pathology or prophylaxis of Malaria. Selection of the winner will be made by the Expert Committee on Malaria. This prize fund was created in

1945 in memory of Dr. T. S. Darling, who was accidently killed during a study mission of the League of Nations Malaria Commission.

BRITISH HONOR FOR BERNARD M. BARUCH

In recognition of the international influence of his activities in advancing the cause of physical medicine, honorary membership in the British Association of Physical Medicine has been granted to Bernard M. Baruch, elder statesman and founder of the Baruch Committee on Physical Medicine. In informing Mr. Baruch of this recognition, Lord Horder, Physician to The King and President of the British Association of Physical Medicine, said "The impetus and encouragement which your generosity has afforded physical medicine is of international importance."

In 1944, Mr. Baruch established the Baruch Committee on Physical Medicine with a grant of $1,100,000 for treatment, training, and research in the field of physical medicine in which his father, Dr. Simon Baruch, was one of the nation's pioneers.

YALE SUMMER SCHOOL OF ALCOHOL STUDIES TO HAVE TWO SESSIONS

The Summer School of Alcohol Studies, conducted annually since 1943 by the Laboratory of Applied Physiology of Yale University, will hold two sessions in 1949; one on the campus of Trinity University at San Antonio, Tex., June 6–29; and one at Yale University, New Haven, Conn., July 8–August 5. The curriculum, consisting of lectures, seminars, and demonstrations, deals with the medical, psychologic, physiologic, psychiatric, sociologic, economic, legal, religious, education, and therapeutic aspects of alcohol problems. The summer school is directed by Elvin M. Jellinek, Sc.D. The lecturers, mainly from the faculties of Yale University and Texas Christian University, include authorities who have done original research in their fields as well as representatives of other national institutions of education, research, treatment or rehabilitation. Applications for the Texas session will be received up to April 1 and for the Yale session up to April 15. Application blanks may be obtained from the Executive Secretary, Summer School of Alcohol Studies, Yale University, New Haven, Conn.

PERSONALS

ODIN W. ANDERSON, Ph.D.,† has resigned as Instructor, Bureau of Public Health Economics, School of Public Health, University of Michigan, to become Associate Professor in charge of the Social Aspects of Medicine, University of Western Ontario, London, Ontario.

ROBERT J. ANDERSON, M.D.,† a former chief of the Tuberculosis Service, California State Department of Public Health, has been appointed Medical Director and Chief of the Tuberculosis Control Division, U. S. Public Health Service.

DONALD B. ARMSTRONG, M.D.,* Second Vice President of the Metropolitan Life Insurance Company, in charge of its health educational and welfare program, has been elected President of the New York Tuberculosis and Health Association, Inc.

HERBERT ARNOLD has become Assistant Sanitary Engineer in the Division of Sanitary Engineering, North Dakota State Health Department, Bismarck.

WILLIAM T. BEATY,† who for the past year has conducted a demonstration in health education with the Ulster County Health Association, joined the New York State Committee on Tuberculosis and Public Health on February 1, as Field Secretary.

JESSIE M. BIERMAN, M.D.,* Professor of Maternal and Child Health at the University of California's School of

Public Health, between January and April was in Germany to take part in a study of maternal and child health under the democratization program, at the request of the Military Government in the American Zone.

MADISON B. BROWN, M.D.,† has been appointed Executive Vice-President and Medical Director of the Roosevelt Hospital, New York City.

ELIZABETH BUTT was recently appointed Director of the Waycross branch laboratory of the Georgia State Health Department, succeeding CARL ADAMS, resigned.

A. J. CASSELMAN, M.D.,† formerly of the Public Health Laboratory of Camden, N. J., became Director of the Bureau of Laboratories, New Jersey State Department of Health.

DUNCAN M. CHALMERS, M.D., has succeeded LEO J. GEHRIG, M.D., as Director, Division of Tuberculosis Control, Alaska Department of Health. He has been chief of the outpatient department and station allergist with the Veterans Administration at Batavia, N. Y.

EDWARD J. CLEARY, has resigned as Executive Editor of "Engineering News-Record," to become Executive Director and Chief Engineer of the Ohio River Valley Water Sanitation Commission. From headquarters in Cincinnati, he will direct the work on stream pollution abatement envisaged in the compact signed a year ago by the governors of the 8 states of the Ohio River Basin.

JAMES S. CULLEYFORD, M.D., Chief of Medical Services, Veterans Administration, Regional Office, Denver, Colo., has been decorated with the Order of the Orange-Nassau with Swords by the Netherlands Government for his outstanding services to Dutch people held in German concentration camps during the recent war.

LOUIS K. DIAMOND, M.D., of the Harvard Medical School and Children's Medical Center, Boston, has been granted temporary leave to serve as Medical Director of the National Blood Program, American National Red Cross, Washington, D. C.

HARRY EAGLE, M.D., since July, 1947, Scientific Director of the National Cancer Institute, is the head of the experimental therapeutics section that has been set up in the new Microbiological Institute of the National Institutes of Health.

NATHAN B. EDDY, M.D., leader in investigating the use of new narcotics for the control of pain in cancer at the National Institutes of Health, has been elected chairman of the Expert Committee on Habit Forming Drugs of WHO.

VIRGINIA B. ELLIMAN, for the past 2 years Director of Nursing Service for the Eastern Area of the American National Red Cross, has been appointed National Director of Disaster Nursing and Nurse Enrollment for the organization.

WILLIAM GRODOWITZ,† has recently transferred from the Marriage and Divorce Analysis Section of the National Office of Vital Statistics to the Statistics Section of the Cancer Institute, Bethesda, Md.

HARVARD UNIVERSITY, CAMBRIDGE, MASS.

The following appointments have been made to the faculty of the School of Public Health:

WILLIAM M. SCHMIDT, M.D.,* associate professor of maternal and child health practice.

ALFRED L. FRECHETTE, M.D.,* Promoted from instructor to assistant professor of public health practice.

CHARLES R. WILLIAMS, M.D., Promoted from instructor to assistant professor of industrial hygiene.

---

* Fellow A.P.H.A.
† Member A.P.H.A.

JOSEPH HIRSH, Ed.D.,* has been appointed a member of the Medical Advisory Commission of the Division of Alcohol Studies and Rehabilitation of the Virginia State Department of Health.

MAX C. IGLOE, M.D.,† is the new head of the Chicago Health Department's District Health Services Division and has also been appointed associate professor in the department of preventive medicine and public health, University of Illinois College of Medicine, Chicago.

ELMORE P. KALBAUGH, M.D., has recently been assigned by the U. S. Public Health Service to serve as Director of the Division of Tuberculosis Control, Arizona State Health Department.

CLAYTON G. LOOSLI, M.D.,† Associate Professor of Medicine, and Director of the Student Health Service of the University of Chicago, has been appointed to take charge of the Division of Preventive Medicine and Public Health in the School of Medicine, where he will be in charge of projects concerned with problems of preventive medicine in both industrial and general public health areas.

MARION MCBEE, for many years Executive Secretary of the New York City Committee on Mental Hygiene of the State Charities Aid Association, has been made Director, division on state and local organization, of The National Committee for Mental Hygiene.

ABBOTT B. MITCHELL, M.D., M.P.H.,* formerly with the Michigan State Department of Health, became Jackson County, Oregon, Health Officer February 1, succeeding A. ERIN MERKEL,† resigned.

PHILIP E. NELBACH,† public health specialist and executive director of the United Yugoslav Relief Fund of America, has been reëlected to the Board of Directors of CARE for 1949.

PHILIP J. RAFLE, M.D., M.P.H.,* New York City Regional Director, New York State Department of Health, has resigned to become Commissioner of Health in Suffolk County, with headquarters at Riverhead, N. Y., succeeding ARTHUR T. DAVIS, M.D., deceased.

NINA RIDENOUR, most recently director, National Committee for Mental Hygiene, division on world affairs, is now Director of the division of education.

DOROTHY ROUSE, has succeeded JANE E. MYERS as Chief of Occupational Therapy of the Veterans Administration Physical Medicine Rehabilitation Service.

HERBERT I. SCHEFFER, M.D.,† has been appointed Director, Bureau of Medical and Hospital Services of the New York City Department of Hospitals. Dr. Scheffer formerly was Medical Superintendent of Metropolitan Hospital, New York City.

CECIL A. Z. SHARP, M.D., M.S.P.H.,* Commissioner of Health for St. Louis County, Missouri, and Assistant Professor of Public Health at Washington University School of Medicine, resigned in November, 1948, to become St. Louis Area Medical Administrator for the United Mine Workers of American Welfare and Retirement Fund.

MARION SHEAHAN,* who recently retired as Director of the Division of Public Health Nursing, New York State Department of Health, Albany, is serving during the spring term as Visiting Associate Professor in Public Health Administration at the School of Public Health, University of California, Berkeley.

RICHARD E. SHOPE, M.D., member of the Rockefeller Institute for Medical Research, New York, N. Y., has been appointed Associate Director of the Merck Institute for Therapeutic Research, Rahway, N. J.

JOSEPH SMITH, M.D.,* has been appointed Superintendent of the Provi-

dence, R. I., Department of Health, succeeding MICHAEL J. NESTOR, M.D., deceased.

CATHERINE SNOW, became Health Educator of the Macon County (Illinois) Tuberculosis and Visiting Nurse Association in January.

ANATOLE A. SOLOW,† formerly a staff member of the A.P.H.A. Committee on the Hygiene of Housing in New Haven, Conn., has left for a 3 months' advisory consultation on town planning to the Israeli Government in Palestine.

R. M. SORENSON, M.D.,* who served for some years with the Iowa State Department of Health in Venereal Disease Control, is now Director of Venereal Disease Control for the Health Department of the City and County of Denver, Colo.

FRANCES A. STOLL,* of New York City, President of the American Dental Hygienists Association, has been named consultant in dental hygiene for the Veterans Administration. She is the first dental hygiene consultant to serve with Veterans Administration.

LEONARD W. TRAGER, Director of the Division of Sanitary Engineering and Technical Secretary of the New Hampshire Water Pollution Board, has resigned to become Chief, New England Drainage Basin, District on Stream Pollution Control, U. S. Public Health Service, with headquarters in Boston.

ELAINE UPDYKE, Sc.D.,† who has served at the State Bureau of Laboratories, Grand Rapids, Mich., as a staff member of the A.P.H.A., under the Pertussis Study Project, has resigned to join the staff of the Communicable Disease Center, U. S. Public Health Service, in Atlanta, Ga.

V. M. WINKLE, M.D.,* formerly Director of the Division of Local Health Administration, Kansas State Board of Health, is now Director of the Kansas City-Wyandotte County Health Department, a full-time unit.

I. JACQUES YETWIN, M.D.,† Chairman of the Springfield, Mass., Chapter of the American Association for the Advancement of Science was appointed Professor of Parasitology at American International College, Springfield, Mass., as of February, 1949.

JAMES ZETEK, of the Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture, has received the Republic of Panama's highest award, The Vasco Nunez de Balboa decoration in recognition of his work on entomological and other biological problems of Panama and the Canal Zone.

Deaths

A. PERRY BANTA,† Associate Professor of Sanitary Engineering, California Institute of Technology (Engineering Section).

GOODMAN BARE, M.D.,† Anderson County Health Department, Anderson, S. C. (Health Officers Section).

JACOB R. BITNER,† Superintendent of Schools, Columbus, Neb. (Public Health Education Section).

HARVEY J. BURKHART, D.D.S.,† Director, Eastman Dental Dispensary, Rochester, N. Y. (Maternal and Child Health Section).

ALLSTON BURR,† Chestnut Hill, Mass. (Unaffiliated).

ISIDOR J. EHLIN, M.D.,† Social Hygiene Clinic, New York City Health Department (Industrial Hygiene Section).

WALTER J. FARRELL, M.D.,† Health Officer and School Physician, Johnson City, N. Y. (Health Officers Section).

CARL J. HAWLEY, M.D.,† Director, Division of Epidemiology, Los Angeles City Health Department (Health Officers Section).

W. SCOTT JOHNSON,* Chief Engineer and Director, Section of Environ-

* Fellow A.P.H.A.
† Member A.P.H.A.

mental Sanitation, Missouri Division of Health, died recently (Engineering Section).

PATRICK J. MONAGHAN,† Newark, N. J. (Engineering Section).

MARY E. MURPHY,† Director of the Elizabeth McCormick Memorial Fund, Chicago, Ill., and internationally known authority on child welfare, died suddenly on December 25, 1948.

JOHN J. SIPPY, M.D.,* Health Officer, San Joaquin Local Health District, Calif., died March 15 (Health Officers Section).

Conferences and Dates

American Public Health Association—77th Annual Meeting. New York, N. Y. October 24–28.

American Society of Medical Technologists. Hotel Roanoke, Roanoke, Va. June 20–23.

American Water Works Association:
69th Annual Conference. Stevens Hotel, Chicago, Ill. May 30–June 3.

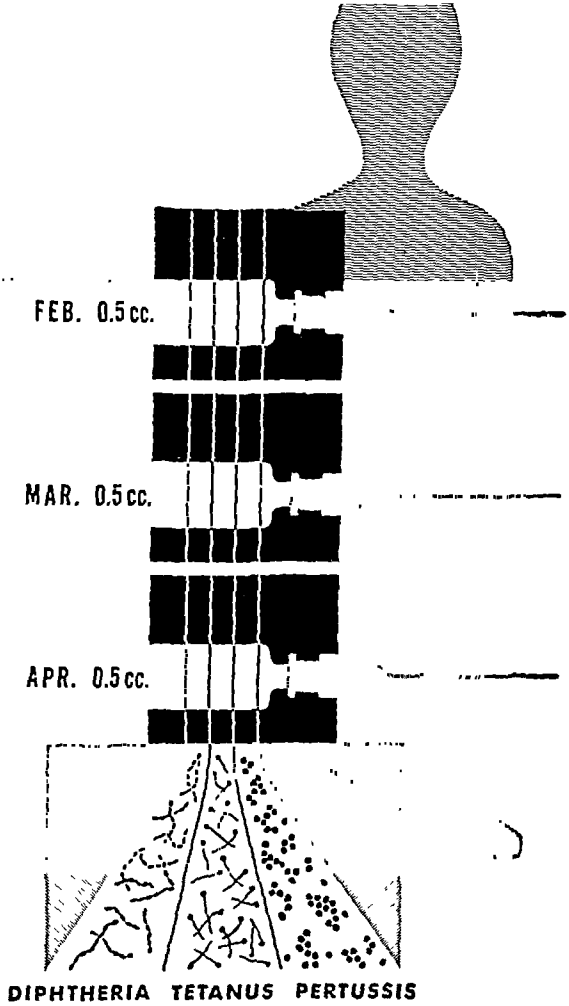
GENUINE Roccal Reg U S Pat Off and Canada BRAND SANITIZING AGENT

The sanitizing properties of quaternary ammonium compounds are so well known to public health officials that little could be said about them that you do not know. Almost everybody in public health work has added the "quats" to the armamentarium he uses in his war on disease.

The question then, is which "quat"? Are they all alike? Which one can I depend on to do the job expected of it *every* time?

In Roccal, the original quaternary ammonium germicide, you are offered a product that is always uniform in quality because it is made under the most rigid controls. Every batch must pass the comprehensive laboratory tests of one of the world's leading pharmaceutical manufacturers. You can depend on Roccal to do a better sanitizing job *every* time!



When you specify a "quat"
BE SURE IT'S GENUINE ROCCAL

How mild can a cigarette be?

In a recent coast-to-coast test, hundreds of men and women smoked Camels—and only Camels—for 30 consecutive days. These people smoked on the average of one to two packs a day. Each week, during the entire test period, throat specialists examined these Camel smokers. A total of 2470 careful examinations were made. The doctors who made the throat examinations of these Camel smokers reported:

"NOT ONE SINGLE CASE OF THROAT IRRITATION due to smoking CAMELS!"

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS

than any other cigarette

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel!

Money-Back Guarantee!

Smoke Camels and test them in your own "T-Zone"—T for taste, T for throat. If, at any time, you are not convinced that Camels are the mildest cigarette you have ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. *(Signed)* R. J. Reynolds Tobacco Co., Winston-Salem, North Carolina.

Here's how the new B-K PR plan can help you

The B-K PR PLAN stands for better patron relations between farmer and dairy plant. As the basis for this, a complete program has been set up by the makers of B-K to help the farmer produce top quality milk through a definite and efficient dairy sanitation program.

This B-K PR PLAN offers the dairy farmer . . . through his fieldman . . . informative films, recordings, literature and other educational material . . . that directs the farmer's attention to the need for positive dairy sanitation.

You can depend on the authenticity and accuracy of the material used in this B-K PR PLAN, for it has been carefully prepared by the makers of B-K Products—the backbone of many quality milk programs. Find out more about the B-K PR PLAN and how you can play a part . . . we'll send full details on request. Write: Dept. PR, B-K Division, Pennsylvania Salt Manufacturing Company, 1000 Widener Building, Philadelphia 7, Pa.

More light on Ice Cream's food value

Now, actual analyses show ice cream to be a better source of vital nutrients than previously believed

It is now established that ice cream can make an important contribution to the daily intake of many dietary essentials.

Heretofore, our knowledge of the individual nutrients of ice cream was based entirely on calculated values. Only recently have actual *analytical* data on the food value of ice cream been made available.

The first complete data on commercial ice cream of specified composition are contained in the work of Dahlberg and Loosli.* For this study, vanilla ice cream was manufactured in a commercial plant according to standard procedures but under scientifically controlled conditions.

These analytical data show that, in general, we had underestimated the nutritive content of ice cream. This was particularly true of riboflavin and vitamin A.

Here are the results of that work:

Nutrient Content of 100 Grams of Vanilla Ice Cream* (approximate measure = ⅙ quart)

Food Energy—206 Calories	Iron—0 12 Milligrams
Protein—3 85 Grams	Vitamin A—548 I U
Fat—12.06 Grams	Thiamine—0 04 Milligrams
Calcium—0 12 Grams	Riboflavin—0.24 Milligrams
Phosphorus—0 11 Grams	Niacin—0 10 Milligrams

It is gratifying to those of us intimately concerned with nutrition problems to know that ice cream is even better nutritionally than we had thought. These reliable figures on the food value of ice cream will meet a need long felt by everyone concerned with planning adequate diets, whether to please normal appetities, or the often difficult appetites of the convalescent and the aged.

*Dahlberg, A. C. and Loosli, J. K. *Nutritive value of commercial ice cream.* J. Am. Diet. Assn *24*:20 (Jan.) 1948.

Candy

MORE THAN JUST FOOD

Although candies are an excellent source of caloric food energy, and supply many valuable nutrients derived from the milk, cream, butter, nuts, peanuts, and eggs used in their manufacture, they provide more than calories and nutrients.

Candies make a worth-while contribution to the joy of living. They are among the foods which provide true gustatory satisfaction. Taken at the end of a meal, they create a sense of having eaten well and are conducive to an aura of satiety which can have a beneficial influence upon the digestive processes.

The child, the housewife, the worker, and the convalescent —all appreciate a piece or two of candy as the finishing touch of the mid-day or evening meal.

THE NUTRITIONAL PLATFORM OF CANDY

1. Candies in general supply high caloric value in small bulk.
2. Sugar supplied by candy requires little digestive effort to yield available energy.
3. Those candies, in the manufacture of which milk, butter, eggs, fruits, nuts, or peanuts are used, to this extent also—
   (a) provide biologically adequate proteins and fats rich in the unsaturated fatty acids,
   (b) present appreciable amounts of the important minerals calcium, phosphorus, and iron;
   (c) contribute the niacin, and the small amounts of thiamine and riboflavin, contained in these ingredients.
4. Candies are of high satiety value; eaten after meals, they contribute to the sense of satisfaction and well-being a meal should bring; eaten in moderation between meals, they stave off hunger.
5. Candy is more than a mere source of nutriment—it is a morale builder, a contribution to the joy of living.
6. Candy is unique among all foods in that it shows relatively less tendency to undergo spoilage, chemical or bacterial.

Diethylcarbamazine

Lederle

Partial view of Lederle Laboratories, Pearl River, New York

This entirely new development in parasitology is an organic compound that does not contain any heavy metals or similar toxic ingredients. It is the result of long and arduous research, during which more than 1,000 organic synthetic compounds were examined by *Lederle.* This product has been tested in India, Africa, Tahiti, Puerto Rico, British Guiana, and the Virgin Islands. It has been found to have the following advantages—

LOW TOXICITY—Previously, antiparasitic drugs of this type exerted a toxicity upon the host only slightly less than the toxicity upon the parasite.

EASE OF ADMINISTRATION—This drug is readily absorbed when given by mouth, and may be given after meals.

STABILITY—This organic substance is stable under tropical conditions.

IMMEDIATE EFFECTIVENESS—The microfilariae are killed almost instantly.

"LAWRENCE"

NEW 700 POUND "AERO-MIST" SPRAYER IDEAL FOR MUNICIPAL INSECT CONTROL PROGRAMS

In addition to its famous L-80 heavy duty mist sprayer "LAWRENCE" now offers in a smaller sprayer, ALL of the exclusive and scientific features, which have made "LAWRENCE" the name to remember in mist sprayers.

Efficient, compact, and economical, the L-40 LAWRENCE AERO-MIST SPRAYER is especially suitable for municipalities where the program is not large enough for the L-80 heavy duty mist sprayer, or for health departments desiring equipment for their own use apart from other municipal operations.

Here is the newest advance in the control of annoying and dangerous insect pests.

Hard-to-get-at spraying areas can be covered easily, quickly, and thoroughly with the L-40 mounted on a small truck or trailer. Like the heavy-duty unit, the L-40 can operate in a 360° circle and on any plane, automatically eliminating blind spots.

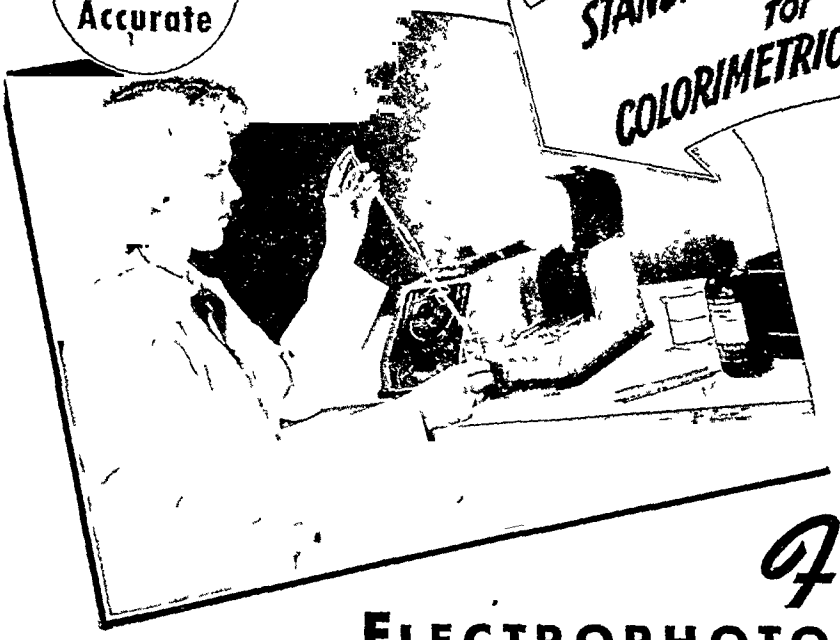
PROTECTS CONSUMERS AGAINST *THEMSELVES!*



Milk contamination can too often occur in the hands of the ultimate consumer. Fork-prying and finger-pushing methods of opening bottles and careless discarding of a separate hood—common in both home and restaurant—constitute real threats to milk purity.

Genuine snug-fitting Seal-Kaps minimize these dangers. Seal-Kaps come off with a simple twisting motion. No need to pry or push. And they *snap back on* as often as necessary to protect securely the pouring lip until the last drop is used. There is no separate hood to discard, because Seal-Kap is disc and hood *in one.* And since it's so convenient to use, consumers automatically enjoy a superior protection—protection *against themselves!*

Accurate

STANDARD INSTRUMENT for COLORIMETRIC ANALYSIS

Fisher ELECTROPHOTOMETER

—eliminates the human factor—

The Fisher Electrophotometer permits colorimetric analyses to be made accurately, quickly and simply wherever the color of the solution varies in a definite manner with the concentration of a constituent. Because of its unique, valuable features, the Electrophotometer is now widely employed for conducting many essential routine analyses and for research.

The Electrophotometer operates from any 110 volt, 50-60 cycle line. With it, the user can detect very slight color intensity differences because the photoelectric system it employs is considerably more sensitive and reliable than the human eye. Once a calibration is made, subsequent analyses can be conducted as rapidly as the simple operations can be performed.

Fisher Electrophotometer, complete with galvanometer, three filters, three 23-ml. absorption cells, manual of typical procedures for use with 110 volts, 50-60 cycle A.C. only $210.00

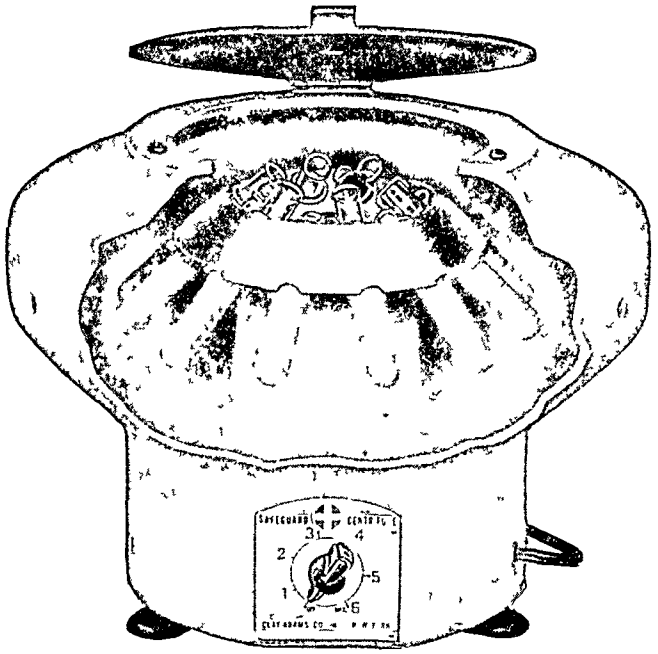
250,000 UNITS
In the Oral Prophylaxis of Gonorrhea

By means of a single orally administered dose of penicillin taken as soon as possible after exposure, and preferably within 2 hours, the development of gonorrhea can usually be prevented. In a recently reported preliminary study,* the incidence of infection was dropped from .43 cases in 3,616 liberties among untreated controls to 2 cases in 1,239 liberties; there is reason to believe the two infections may have been due to failure to take the medication after exposure.



The subjects received a single buffered tablet of penicillin containing 250,000 units. No contraindications to this practice were detected. Ideally, the penicillin should be taken within two hours after exposure, but some protection is afforded even after an interval of six to eight hours.

Tablets Buffered Crystalline Penicillin G Potassium-C.S.C., individually wrapped in foil, are supplied in two potencies: 250,000 units each and 500,000 units each, in boxes of ten. Either may be employed, depending upon the clinical situation.

*Eagle, H.; Gude, A. V.; Beckman, G. E.; Mast, G.; Sapero, J. J., and Shindledecker, J. B.: Prevention of Gonorrhea with Penicillin Tablets. Preliminary Report, Pub. Health Rep. 63:1411 (Oct. 29) 1948.

ADAMS 12-PLACE ANGLE-HEAD CENTRIFUGE

FEATURES

Utilizes the angle principle by suspending the tubes at a fixed 52° angle, thus achieving a faster rate of sedimentation and more complete sedimentation with finely dispersed particles.

Accommodates 12 blood tubes of the commonly used sizes, 6 blood tubes and 6 15-ml. tubes, or 6 15-ml. tubes.

Can be used for micro and semi-micro work by substituting the proper shields.

Head is made of a special aluminum alloy, precision-machined for accurate balance.

Base and guard bowl are an integral aluminum casting, carefully inspected to insure against flaws.

Rheostat provides an "off" position and allows for continuous speed control.

Rubber suction feet absorb all vibration and keep the centrifuge from creeping, even on a glass surface.

Finished in attractive gray hammertone.

Operates on 110 volts, AC and DC.

CT-1230/D ***Adams Safeguard Angle-Head Centrifuge, 12 Place;*** complete with head and 12 brass shields; without glassware_____each **$105.00**

POUR DIRT AWAY with Rexair

Wouldn't you like to get rid of dusty vacuum bags forever? Wouldn't you like to pour dust away as easily as dirty dishwater?

You can, with Rexair—the amazing new home appliance that washes your dust away. Rexair collects dust in water; you just pour the water down the drain and flush—dust and dirt go with it.

When you clean with Rexair, you clean *clean*. Rexair has no porous bag through which dust can escape back into the air you breathe. Instead, the air passes through a churning bath of water which wets down the dust and returns only dust-free air to the room. Wet dust cannot fly, and dust cannot escape from Rexair's water basin.

Rexair washes the air in your home, humidifies, vaporizes medicaments, even scrubs floors. See the Rexair before you buy a humidifier, a vaporizer, or even a vacuum cleaner. Over 1,000,000 in use.

FREE BOOK: Send for this free, illustrated 12-page book. Shows how Rexair even cleans the air you breathe. REXAIR DIVISION, MARTIN-PARRY CORP. Box 964, Toledo 1, Ohio, Dept. P-49

When the Diet Assumes

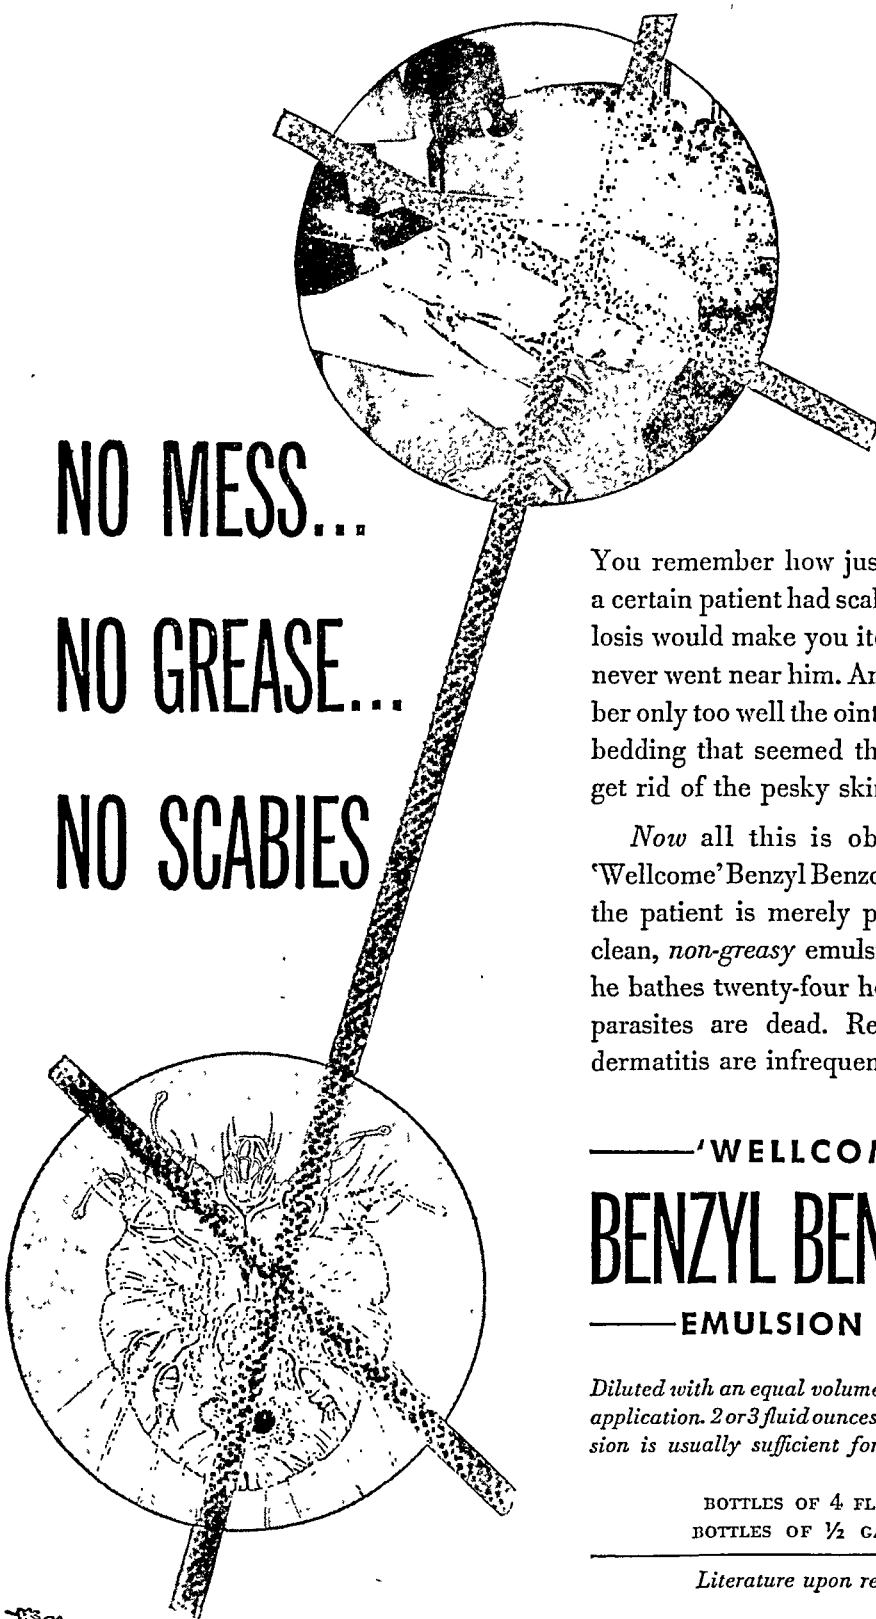
THERAPEUTIC IMPORTANCE

IN MANY gastrointestinal affections, and in the management of the many systemic conditions in which diet assumes therapeutic importance, the cereal serving is particularly valuable.

Consisting of breakfast cereal, milk, and a teaspoonful of sugar, it provides an abundance of essential nutrients and caloric food energy. This time-honored combination is easily digested, bland, and readily utilized. It is well tolerated in the presence of many gastrointestinal conditions and offers the additional advantages of taste appeal, variety, ease of preparation in the home, and economy.

The over-all nutritive value of the cereal serving—1 ounce of ready-to-eat or hot cereal,* 4 ounces of milk, and 1 teaspoonful of sugar—is shown in this table:

CALORIES	202	PHOSPHORUS	206 mg.
PROTEIN	7.1 Gm.	IRON	1.6 mg.
FAT	5.0 Gm.	VITAMIN A	193 I.U.
CARBOHYDRATE	33.0 Gm.	THIAMINE	0.17 mg.
CALCIUM	156 mg.	RIBOFLAVIN	0.24 mg.
		NIACIN	1.4 mg.



Composite average of all breakfast cereals on dry weight basis

BURROUGHS WELLCOME & CO. (U.S.A.) INC., 9 & 11 EAST 41st ST., NEW YORK 17

now you can obtain **both**

a RAPID peak concentration of serum penicillin

and

a SUSTAINED *therapeutic* concentration

with a single injection from a single container

FLO-CILLIN "96"—the *original* 96-hour repository penicillin formulation—is now available with a *plus*. Soluble Penicillin G Potassium—100,000 units per cc.—has been added to the FLO-CILLIN "96" formula. The soluble potassium penicillin is absorbed promptly, with a resulting initial penicillin blood concentration sufficient to overwhelm invading bacteria at the outset. The insoluble Procaine Penicillin G, with water-repellent aluminum stearate in oil, is absorbed slowly and regularly over a period measured in days. Thus, with a single injection from a single container, it is now possible to obtain an initial *peak* penicillin blood level, together with a *therapeutic* blood level which is sustained for 96 hours in approximately 90 per cent of patients.*

CONSTANTLY FLUID

REQUIRES NO PROLONGED SHAKING

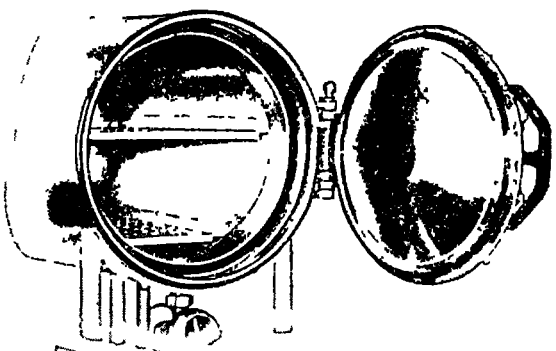
Compare the precision-efficiency of "AMERICAN" LABORATORY AUTOCLAVES

Steam Jacketed Autoclaves fully capable of drying fabrics—thus accommodate all customary pressure sterilizer loads.



Rapid performance always available because the sterilizer is kept heated between runs by steam in the jacket.

Single Wall Type unexcelled for bacteriologic media, solutions and the many performances required in routine laboratory procedures but without drying facilities for wrapped supplies.

Units include special valving—

- For pressure steam sterilization of bacteriologic media and solutions.
- For coagulation and sterilization of blood serum.
- For non-pressure (streaming steam) sterilization.

These superior Autoclaves also feature controls permitting the exact duplication of a given performance, and are simplified so that even other than highly skilled technicians can operate them with utmost efficiency.

PROTECTS AGAINST PREMATURE EXPLOSIVE OPENING of full diameter door by a pressure actuated clutch preventing rotation of the handwheel until pressure is exhausted.

NEW SPENCER COLONY COUNTER

Even the pinpoint bacterial colonies are easy to count —quickly and accurately — with this new Spencer Dark Field Quebec Colony Counter. Employing the principle of the dark field microscope, it has a unique annular reflector which illuminates the specimen symmetrically with oblique rays of light and leaves the background subdued. As a result it provides:

1. Remarkably uniform illumination— the colonies are lighted from all sides.
2. Greater brilliance— reflector collects and concentrates the light rays.
3. Freedom from glare— only light reflected from the specimen reaches the eyes of the observer.
4. Enclosed illuminating system — protected from dust, yet permitting easy replacement of the household 40 watt lamp.

Equipped with a standard 1.5x lens, this compact, efficient instrument will be welcomed by health departments, hospitals, dairies, breweries, canneries— wherever colony counts are made. Write dept.R-19 for details.

THE NINTH EDITION

of

STANDARD METHODS FOR THE EXAMINATION OF DAIRY PRODUCTS

is now available

This manual, prepared by the Committee on Examination of Milk and Milk Products, outlines procedures for the routine microbiological and chemical examinations of the more common dairy products used as food. It includes directions for enumerating, isolating, and identifying members of the coliform group, *Brucella,* streptococci, tubercle bacilli, *Salmonella,* pathogenic *Shigella,* and enterotoxigenic staphylococci.

The resazurin reduction method for the examination of fluid milk is included in this edition. Procedures are given for the examination of condensed milk, dried milk, evaporated milk and of fruits, nuts, flavoring and coloring materials, eggs and egg products, sweetening ingredients and stabilizers when used as ingredients in frozen desserts.

The primary aim in the new edition is to aid the laboratory worker by maintaining uniformity of arrangement and style, by using a system of simple cross references, and by improving the index. To do this, the first chapter on "Selection and Interpretation of Quality Tests" is organized for the guidance of the administrator. The succeeding twelve chapters, now relatively free from interpretive and explanatory matter, provide tried and tested methods for the laboratory worker. A group of "Screening Tests," which do not have approval for unqualified use, but which permit more frequent examinations than otherwise could be made, appear in the last chapter.

The thirteen chapter headings are listed below.

1. Selection and Interpretation of Quality Tests
2. Microbiological Methods for Milk and Cream
3. Detection of Special Bacterial Groups or Species
4. Microbiological Methods for Butter
5. Microbiological Methods for Cheese
6. Microbiological Methods for Frozen Dessert Ingredients
7. Microbiological Methods for Frozen Desserts
8. Sterility Tests for Dairy Equipment
9. Tests for Sediment and Extraneous Matter in Dairy Products
10. Determination of Vitamins
11. Phosphatase Methods to Determine Pasteurization
12. Chemical Methods
13. Screening Tests

Public Health

A CAREER WITH A FUTURE

The American Public Health Association has prepared a 20 page illustrated booklet describing the field of public health—its scope, requirements and opportunities.

The purpose of the booklet is recruitment.

See that high schools and colleges in your neighborhood use this booklet. Distribute it when you tell students about the public health jobs in your city and state. Hand it to applicants at your office and see that public libraries have it.

"Public Health—A Career With a Future" discusses educational qualifications and employment opportunities and lists schools where public health training may be secured including the institutions accredited by the Association to give the degree of Master of Public Health.

It will save your time and attract those who will become the public health workers of tomorrow.

Single copies are 15 cents each; 25 to 49 copies are 12 cents each; 50 copies and over are 10 cents each.

The Influence of Timing On Protein Utilization

The biologic importance of complete protein in the daily diet takes on new significance in the light of recent research on the influence of timing upon protein utilization.[1,2]

Protein-depleted animals, maintained on an otherwise adequate diet, rapidly regained weight when fed their complete ration of the ten essential amino acids. When, however, these ten amino acids were not provided simultaneously—five were given at one feeding and the other five in a feeding two hours later—recovery did not occur.

These studies strongly suggest that efficient protein utilization requires simultaneous absorption of the indispensable amino acids. New emphasis is thus given to the rationale of routinely including biologically complete protein in all meals to assure optimal utilization of all the protein ingested.

Meat is an outstanding source of complete protein. Regardless of cut or kind, whether fresh, cured, or canned, all meat contains the ten indispensable amino acids capable of satisfying every protein need of the organism. And, all meat is of excellent digestibility—from 96 to 98 per cent.

Penicillin Inactivation

with

BACTO-PENASE

Bacto-Penase is a sterile thermolabile biological extract possessing the capacity to neutralize the antibiotic properties of all known types of *penicillin*. It is non-toxic to microörganisms and is therefore particularly satisfactory for use in the sterility testing of *penicillin* or products containing *penicillin*, and in determining the microbial counts on *penicillin*-containing products. BACTO-PENASE is recommended as a penicillinase for use in official procedures for sterility testing of *penicillin*. It is also recommended for use in media for culturing organisms from blood and other body fluids containing *penicillin* and for estimation of *penicillin* levels in such fluids.

PENICILLIN STERILITY TESTS

BACTO-PENASE in a concentration of 1 ml. per 15 ml. of Bacto-Fluid Thioglycollate Medium inactivates 50,000 units of *penicillin* in 40-48 hours incubation or 10,000 units of *penicillin* in 18 hours incubation.

BLOOD CULTURE

BACTO-PENASE is recommended for use in media for culturing blood or other body fluids containing *penicillin*. It is suggested that 1 ml. of BACTO-PENASE be added to 100 ml. of culture media such as Bacto-Brain Heart Infusion with P.A.B. or Bacto-Brain Heart Infusion with P.A.B. and Agar for this purpose. Media so prepared will inactivate the maximum amount of *penicillin* and sulfonamides present in 10 ml. or less of blood or other body fluids, and will also inactivate up to 1000 units of *streptomycin*.

Stability. BACTO-PENASE and media containing this penicillinase are stable when stored at refrigerator temperatures (2°-6°C.).

Bacto-Penase Concentrate. BACTO-PENASE is available in concentrated form as BACTO-PENASE CONCENTRATE, 1 ml. of which neutralizes 500,000 units of *penicillin*. BACTO-PENASE CONCENTRATE is recommended in the sterility testing of *penicillin*.

BACTO-PENASE and BACTO-PENASE CONCENTRATE are supplied in standard packages of one-half dozen and one dozen screw cap tubes of 20 ml. each.

Descriptive literature is available upon request.

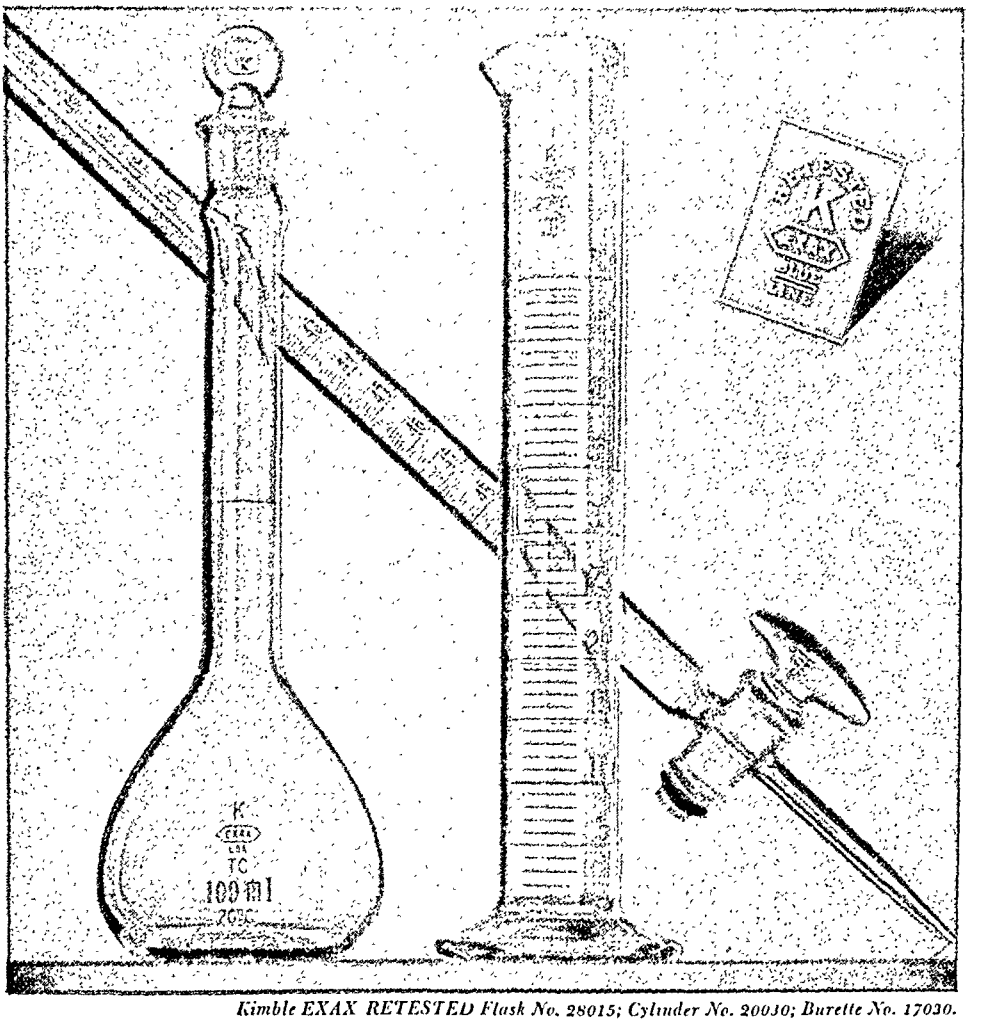
'WELLCOME' BENZYL BENZOATE EMULSION for Scabies

No longer are slow, greasy ointments with their attendant messiness necessary to treat scabies. In their stead has come quick, easily applied, highly parasiticidal benzyl benzoate emulsion. • • • Writes Mackenzie[1]: "The ease and speed with which the application can be carried out...rapidity of cure, and the almost immediate relief from itching combine to make it a satisfactory remedy from both the clinical and the public health aspects."

'WELLCOME' BENZYL BENZOATE EMULSION 50%

Application: Following a thorough soap and water bath, the emulsion (diluted to 25%) is painted on the entire body, allowed to dry, and *then reapplied*. A warm bath, 24 hours later, completes the treatment.



Bottles of 4 fl. oz. and ½ gal.

1. Mackenzie, I. F.: Brit. M. J. 2:403, 1941.

Kimble EXAX RETESTED Flask No. 28015; Cylinder No. 20030; Burette No. 17030.

There's no substitute for EXAX RETESTED quality

EXAX RETESTED is America's No. 1 choice for accurate laboratory determinations simply because it is made and intended for that purpose. EXAX won't bounce, but it is thoroughly annealed for toughness . . . will stand everyday handling and usage.

The great value of EXAX RETESTED lies in certain exclusive advantages. It is a special formula of glass, precision-made by specialty craftsmen.

The fine deep graduations are of a type which readily accepts the permanent fused-in blue filler. *And*... all calibrations are marked and checked and *retested* with standards of highest precision.

So remember, if accuracy and fitness for the job are important, there is no substitute for EXAX RETESTED glassware.

Look for the Kimble "K", the visible guarantee of invisible quality.

Higher calcium standards for adults put more emphasis on Dairy Products

Research recognizes the benefits to be derived from more calcium in the adult diet. Accordingly, calcium standards were increased when Recommended Dietary Allowances* were revised.

Without milk or its products, it is almost impossible to meet daily calcium needs with common foods. This is especially true in view of the recently revised calcium standards for the average adult.* A re-examination of requirements has resulted in raising the recommended daily allowance for calcium from 0.8 gm. to 1.0 gm. per day for normal adult maintenance at all activity levels. New information on the importance of calcium in the nutrition of adults, and on the variation in the ability of aging individuals to assimilate calcium, is responsible for the higher recommendation. The evidence supports the conclusion that while people can adjust themselves to less they are not so well off in the long run.*

Milk Assumes Responsibility. Milk is superior to all other foods as a source of calcium. Fortunately, milk is our most economical as well as our richest food source of this vital mineral. To obtain any sizable proportion of the daily calcium need from other common foods, it would be necessary to consume them in such large amounts that the expense as well as the quantity to be eaten would be prohibitive. Then, too, there is evidence that the calcium from milk and its products is maximally utilized by the body.

Milk "Shares the Wealth" of Calcium. While milk could stand alone as a single source of calcium for people of all ages, it is generously assisted by cheese and ice cream. Cheese supplies varying amounts of calcium, depending upon its method of manufacture. Cheddar cheese, and other "yellow" cheeses, contribute substantially to the intake, even when eaten in small amounts. Ice cream, too, is an outstanding source of calcium. Research has indicated that the calcium in ice cream is as readily put to use by the body as that of milk, and that the rate of use does not change when ice cream, in part, replaces milk in the diet.

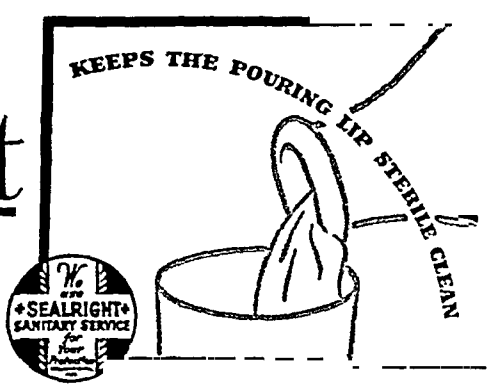
(with apologies to Tennyson)

If there is one place on a milk bottle which should never be promiscuously handled—that place is the pouring surface.

The reason is obvious.

Every drop of milk in the bottle must pass over that pouring surface before it can be used.

No wonder health authorities and public spirited dairies are so insistent upon *sealed* protection of that pouring surface from dairy to home.



In every state and in many foreign countries, Sealright Sealon Hoods are keeping milk bottles safe against contact with hands, melting ice, rain, snow or dusty air. *They protect all the way to the home.*

The BIGGEST VALUE in VOLUMETRIC WARE!

Corning does many things to give you the biggest value in volumetric ware. Made of PYREX brand glass No. 774, it's tops in quality. This pays off in longer service life and in greater accuracy.

In its chemical stability and resistance to thermal and physical shock, PYREX volumetric ware is outstanding. You can use it for so many different applications that it gives you greater working flexibility.

The design of this ware is also unique. PYREX brand cylinders are made with hex bases. They can't roll. Some types are made with reinforced tops. This minimizes breakage from accidental tipping. Each piece is individually calibrated for accuracy. This all adds up to bigger value.

And, PYREX volumetric ware is available with or without "Lifetime Red" graduations. When you specify "Lifetime Red," you know that the graduations will be permanent and *always* can be read. So when you order volumetric ware from your Corning Laboratory Supplier, specify PYREX brand and get extra value.

EASILY DIGESTED

PROMPTLY UTILIZED

THE convalescent patient appreciates more than just the attractiveness and the appetite appeal of the breakfast cereal on the meal tray. He appreciates also the satiety value and the easy digestion of this nutritious breakfast dish. Following illness, when food interest ordinarily is low and the digestive processes are slowed, all of these values may mean much to the progress of the patient.

The breakfast cereal serving—breakfast cereal, milk, and sugar—is singularly adapted to the nutritional needs in illness and convalescence when the diet frequently has to be limited. Its nutrient content of protein of high biologic value, of carbohydrate and fat, and of vitamins and minerals is exceptionally well balanced. Its appealing taste makes it a universally accepted favored dish. The many kinds of breakfast cereals available make for welcome variety. Because of its bland taste, the cereal serving blends readily with all other foods.

The nutrient composition of the breakfast cereal serving made from 1 ounce of breakfast cereal,* 4 fluid ounces of milk, and 1 teaspoonful of sugar is shown in the table.

The presence of this seal indicates that all nutritional statements in this advertisement have been found acceptable by the Council on Foods and Nutrition of the American Medical Association.

A RESEARCH AND EDUCATIONAL ENDEAVOR DEVOTED TO THE BETTERMENT OF NATIONAL NUTRITION

Long lines of black ants attracted to madhumeha, "honey urine," led the ancient Hindu wise men to observe and recognize diabetic urine, which they described as "astringent, sweet, white and sharp." Avid insects became an acknowledged means of diagnosis. Almost equally primitive methods of urine-sugar detection remained in effect for a score or more of centuries, until modern copper reduction tests were perfected, refined and simplified.

Simplest of all today is the reliable *Ames* tablet method, performed in a matter of seconds. Urine-sugar levels are determined by direct, easily-learned steps. The use of *Clinitest* (Brand) reagent tablets has eliminated the inconvenience of external heating. Interpretation of routine urine-sugar testing follows readily from color scale comparison.

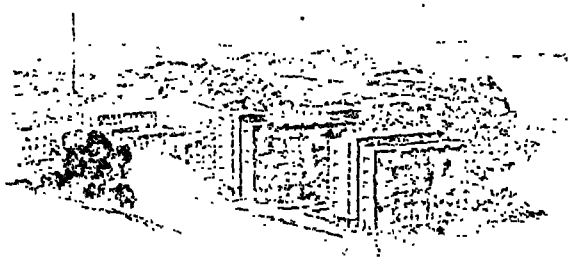
International Refrigerated Centrifuge

Centrifugation under controlled temperatures at or well below 0° C. offers new possibilities to the biochemist. The cancer program —virus investigations—poliomyelitis research —enzyme research—low temperature solvent fractionation—all have benefited by the use of this new research tool. Countless other applications are waiting the guidance of the research scientist.

The International Portable Refrigerated Centrifuge, Model PR-1, is now equipped with a larger capacity compressor. Centrifuge speeds and capacities remain unchanged, but much lower controlled temperatures are now possible. For example, with six 100 ml. tubes at 5000 r.p.m., temperatures as low as -15° C. can be maintained; with four 250 ml. bottles at 2600 r.p.m., -8° C.; with four 25 ml. tubes at 18,000 r.p.m., -5° C.



Here is a scientifically designed research instrument definitely worth investigating. Write for descriptive Bulletin RC, 1949.

HETRAZAN*

Diethylcarbamazine

Lederle

Partial view of Lederle Laboratories, Pearl River, New York

This entirely new development in parasitology is an organic compound that does not contain any heavy metals or similar toxic ingredients. It is the result of long and arduous research, during which more than 1,000 organic synthetic compounds were examined by *Lederle*. This product has been tested in India, Africa, Tahiti, Puerto Rico, British Guiana, and the Virgin Islands. It has been found to have the following advantages—

LOW TOXICITY—Previously, antiparasitic drugs of this type exerted a toxicity upon the host only slightly less than the toxicity upon the parasite.

EASE OF ADMINISTRATION—This drug is readily absorbed when given by mouth, and may be given after meals.

STABILITY—This organic substance is stable under tropical conditions.

IMMEDIATE EFFECTIVENESS—The microfilariae are killed almost instantly.

FOR ITS UNUSUAL MERIT

KWELL® OINTMENT

THE outstanding scabicidal and pediculicidal properties of Kwell Ointment were again reaffirmed in a recently reported study. Cannon and McRae[1] treated 100 cases of scabies and achieved clinical cures in all patients. Sixty-one patients required but one application, 36, two applications, and the remaining 3, three applications. Subjective relief was apparent in 2 to 3 hours in a few patients, and was complete in 24 to 48 hours in half the patients. No instance of dermatitis was observed, and no evidence of sensitivity was obtained on subsequent testing. Kwell Ointment was applied in the presence of secondary infection without adverse results; in fact, control of the infestation permitted prompt healing of the superimposed dermatitis. Equally good results were obtained in a small series of pediculosis corporis and pubis.

This outstanding performance of Kwell Ointment has been previously reported.[2,3] Its sound clinical and experimental background merit its use whenever a diagnosis of scabies or pediculosis is made.

Kwell Ointment containing 0.5 per cent of the gamma isomer of 1, 2, 3, 4, 5, 6,-hexachlorocyclohexane is available on prescription in 2 ounce and 1 pound jars. Literature to physicians on request.

Here's what throat specialists reported about Camel Mildness—

In a recent coast-to-coast test, hundreds of men and women smoked Camels—and only Camels—for 30 consecutive days. They smoked on the average of one to two packs a day. Each week throat specialists examined the throats of these smokers, a total of 2470 careful examinations, and reported

"NOT ONE SINGLE CASE OF THROAT IRRITATION due to smoking CAMELS"

Money-Back Guarantee!

Try Camels and test them as you smoke them. If, at any time, you are not convinced that Camels are the mildest cigarette you've ever smoked, return the package with the unused Camels and we will refund its full purchase price, plus postage. (*Signed*) R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

According to a Nationwide survey:

MORE DOCTORS SMOKE CAMELS *than any other cigarette*

Doctors smoke for pleasure, too! And when three leading independent research organizations asked 113,697 doctors what cigarette they smoked, the brand named most was Camel!

A New Aid to Public Health

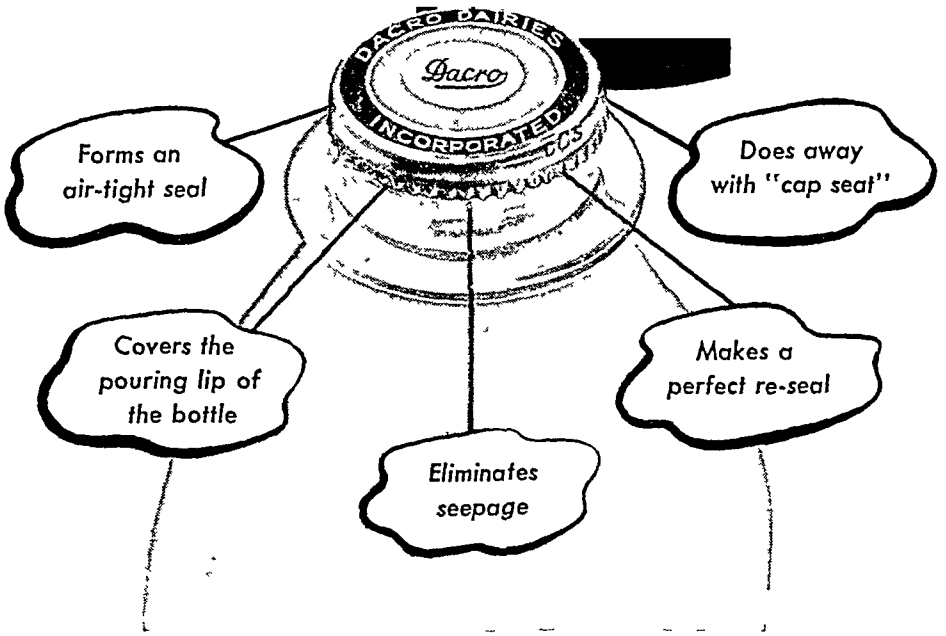
by

"LAWRENCE"

NEW 700 POUND "AERO-MIST" SPRAYER IDEAL FOR MUNICIPAL INSECT CONTROL PROGRAMS

In addition to its famous L-80 heavy duty mist sprayer "LAWRENCE" now offers in a smaller sprayer, ALL of the exclusive and scientific features, which have made "LAWRENCE" the name to remember in mist sprayers.

Efficient, compact, and economical, the L-40 LAWRENCE AERO-MIST SPRAYER is especially suitable for municipalities where the program is not large enough for the L-80 heavy duty mist sprayer, or for health departments desiring equipment for their own use apart from other municipal operations.



Here is the newest advance in the control of annoying and dangerous insect pests.

Hard-to-get-at spraying areas can be covered easily, quickly, and thoroughly with the L-40 mounted on a small truck or trailer. Like the heavy-duty unit, the L-40 can operate in a 360° circle and on any plane, automatically eliminating blind spots.

STREAMLINED

Siva

1949 MODEL

A modern W&T Chlorinator—like the Hindu God Siva—is truly a multi-armed instrument, economically performing sewage plant duties that make operation easier, give extra plant capacity and result in better over-all treatment to help meet more stringent stream pollution controls.

For example, W&T Chlorinators such as the Program Controlled Chlorinator are being used in sewage plants for:

(1) Disinfection
(2) Odor Control
(3) Reduction of corrosion and concrete disintegration
(4) B.O.D. reduction
(5) Improvement of settling
(6) Conditioning of return supernatant liquid
(7) Prevention of sludge bulking
(8) Sludge conditioning
(9) Adjunct in chemical precipitation
(10) Trade waste control
(11) Effluent sterilization

Best of all, this "Siva" is available to work for you at wages that everyone can afford. The average installation represents less than 1% of total plant cost.

To get the complete story on the multiple advantages of sewage chlorination and on W&T Equipment backed by over 35 years' experience, call in your W&T Representative. He'll be glad to help you.

Recent Observations on the British National Health Service

HUGH R. LEAVELL, M.D., DR.P.H., F.A.P.H.A.

Professor of Public Health Practice, Harvard School of Public Health, Boston, Mass.

THE British National Health Service is neither as bad as painted by those who fear compulsory health insurance in the United States, nor as good as the British medical profession and the Ministry of Health would like to see it and hope it will become. We in the United States can learn much from this experiment now being conducted almost under our eyes, if only we can look at it without emotional blindness. While the problem of the British is in many respects not comparable to our own, there are certainly sufficient similarities in background and outlook to make their experience valuable to us in developing our own plans for more adequate medical care. Failure to see defects in the present British situation, however, may be almost as dangerous for us as would be acceptance at their face value of many current misrepresentations which are the despair of officials of the British Medical Association.

This note is in no wise intended to be an exhaustive study of the British system, but represents a report on a recent (February, 1949) appraisal of the situation with the hope that it may be useful to us in the present tense atmosphere in which discussion of federal medical care proposals is taking place. The writer was in London for a year during the war with opportunities to see existing physical facilities and get a picture of medical practice as it was carried on prior to the National Health Service Act. During the summer of 1947, nearly two months were spent in Great Britain after passage of the Act during the stages of planning for its operation. During the first two weeks of February, 1949, a third visit was made, concentrating on aspects of the Service where difficulties were reported to have arisen. Practitioners, medical society representatives, and public officials concerned with operation of the Service were asked to give their frank reactions; to point out where snags had arisen and where certain services had not developed entirely as expected. Attempts were also made to determine reactions of the general public to the plan by talking to the "man in the street" on the street and wherever else he could be induced to talk.

Before forming our judgments, certain

important concepts must be borne in mind. The broad, basic principles of the plan are generally accepted by the Conservative party as well as the Labor party. The British Medical Association also supports them as it has for a number of years, since it recommended broadening the old insurance system set up by Lloyd George in 1911–1912. Voluntary hospitals were rapidly going bankrupt and realized the necessity for government support. The several Spens Committee's proposals on compensation for varying types of practitioners have met with general acceptance.

The existing situation must also be judged on the basis of practices and standards prevailing prior to the appointed day, July 5, 1948, when the new Act became effective, rather than using current American customs of practice as our sole criterion. For example, even in the past, general practitioners had little practice in hospitals and used nursing homes for private patients requiring hospital type care. They usually had little auxiliary help in the way of clerks, nurses, or technicians in their offices, and few had laboratory services readily available for their patients. Nearly half the population was covered for general practitioner services only under the insurance scheme for employed people below a specified income limit. About one-third of the general hospital beds were in voluntary hospitals and two-thirds were operated by local governmental authorities. The wartime Emergency Medical Service developed a skeleton regional plan of hospital organization, but much of this had lapsed following the end of the war. Local public health authorities were generally responsible for running the local governmental hospitals, and services in a number of areas, especially London, had shown great improvement over conditions in these hospitals prevailing when taken over in 1929 from the Poor Law Guardians. Dental conditions among the general public were notably poor. Dentists were relatively few and even many of those licensed were more or less irregular practitioners blanketed in when the long delayed licensing programs became effective. Great numbers of people procured their eyeglasses from 5 and 10 cent stores without benefit of skilled eye examinations.

The present plan is not really an insurance scheme, since only about 10 per cent of the costs are paid by earmarked contributions from individuals and their employers; the remaining costs being paid out of general tax revenue. Participation of doctors and citizens under the new plan is entirely voluntary and provision is made for the continuation of private practice. The hospitals, however, are now essentially all owned by the government. Scotland and Northern Ireland have separate though similar schemes from England and Wales. A last, but by no means unimportant, point to be borne in mind is that it is still entirely too early really to judge the success or failure of the new plan which has not yet had even a single full year of operation.

The administrative structure itself would be considered unwieldy by American standards, but despite its complexity, it may be that the British will make it work. Four administratively distinct units render services at the local levels: The regional hospital boards (14 in England and Wales—responsible for hospitals and specialist services); the teaching hospitals (36); the local executive councils (responsible for general practitioners; dentists; pharmaceutical, and supplementary eye services); and the local public health authorities (responsible in addition to usual public health activities, for ambulance service, the provision of health centers, home nursing service—much of which was formerly the primary responsibility of voluntary agencies—domestic help in the home and "after care"). Each of

these four types of administrative units is responsible to the Ministry of Health, but there is *no* authoritative local coordinating unit.

Let us now examine the four branches of service to see where difficulties have arisen up to the present time. The teaching hospitals are administratively under regional boards in Scotland because the Scots consider them such an essential part of the regional hospital system that they could not be separated. In England and Wales, it was thought important to maintain as much autonomy for the teaching units as possible. All medical schools are full, with long lists of applicants for admission. There is no indication that young men are being deterred from going into medicine because of the new Service.

The regional hospital boards are composed of persons outstanding in the community, and have not been stacked with political appointees. Each board has a medical executive officer of high quality; many having been drawn from public health ranks. Functioning under each board are a number of hospital management committees, each with a lay executive secretary. Each committee is responsible for 8 to 10 hospitals—general, specialized, chronic and convalescent. These groups of hospitals are being integrated into hospital systems more or less complete in themselves, except that at present mental hospitals are operated by the regional boards as a somewhat separate system.

All services of specialists are under the direction of the hospital management committees and the regional boards. Neurosurgery, thoracic surgery, and plastic surgery are usually handled on a regional basis. There are no certifying boards for specialists in Great Britain at present and none are contemplated. However, a committee in each region is now reviewing qualifications to determine which men are actually specialists, and dividing them by grades of seniority. This process is to be completed by July 5, 1949, and new contracts and salaries will be based upon these reviews. A National "Awards" Committee is establishing lists of outstanding specialists who will receive additional compensation. Tables of organization are being developed to specify how many specialists of each type are needed for a given number of hospital beds and population groups. Many specialists are working on a part-time basis, because if even a small portion of their time is devoted to private practice income tax reductions are allowed for costs of operating automobiles, offices, etc.

Clinical pathological services are provided in the hospitals and are available to general practitioners only on a consultation basis at present. Patients may not be referred simply for certain laboratory services, but must be sent to a medical member of the hospital staff who determines whether or not laboratory services are considered necessary. This approval is automatic and simply constitutes a complicating administrative factor. Budgets now being presented by the regional hospital boards show considerable increases over previous operating costs. Numbers of new specialists are being requested and salaries for nurses and other personnel have increased a good deal. There is much deferred maintenance accumulated during the war years, and new buildings are being sought. It seems that the regional hospital boards in this first budgetary process, are "testing" the Ministry of Health to see how far it will allow them to go financially. Medical hospital superintendents who operated most of the governmental hospitals in the past, feel that they are not receiving suitable recognition and that the new system apparently favors lay hospital superintendents.

There are shortages of beds, and it is pointed out that the very lowest in-

come group is now in a less favorable position regarding hospitalization than formerly when welfare officers were usually able to get this lowest income group admitted without delay. Now they must take their turn, and the middle income group has an equal chance for admission to hospitals.

Specialist consultation services are available to general practitioners without too much delay except in certain special fields, such as dermatology. There is definite evidence that the hospitals and specialist service are being better integrated than was possible previously, and that attractions of the specialist service are such that a very large proportion of the younger men will want to become specialists rather than to go into general practice, due to higher compensation, greater professional opportunities, and prestige. Greatly increased numbers of candidates are applying for the higher qualifications of the Royal Colleges, the examinations of which will presumably have to become more rigid than ever before.

Each local area has its own local executive council and these councils are experiencing probably the greatest difficulties of the entire service at present. General practitioner services are paid for on a capitation basis and each practitioner will receive between $3.20 and $3.60 per annum for each patient on his list. No general practitioner may have more than 4,000 patients on his panel. There are in general, three types of general practitioners each of which has fared somewhat differently under the new system. In industrial areas where private practice in the past depended almost entirely on dependents of insured workers, nearly everyone is now on the panel, and compensation is higher than previously. Panels tend to be full and offices are crowded. Many more minor ailments are treated than formerly, and patients present themselves in earlier stages of illness than before. Mothers tend to bring their whole families to the doctor's office. When home visits are made, doctors are often asked to see more than one patient. It is not at all uncommon for general practitioners in urban areas to see 40 to 60 patients daily in their offices and to make from 6 to a dozen or more home visits. All patients on a given panel may be living within a mile of the doctor's office so that practices of this type are quite concentrated. The more experienced doctors feel they can handle 3,000 patients without difficulty. Some of them even say they can do a good job with 4,000 patients, though it requires a nice sense of discipline and experience in detecting emergency needs.

Practitioners in rural areas have suffered because of the sparse population, which prevents their caring for a full panel. Recent adjustment in the mileage fee has compensated somewhat for this problem, though it still remains difficult, and rural practitioners have in general suffered losses in overall compensation. General practitioners working in well-to-do suburban areas who depended on a relatively small number of private patients have suffered material financial losses. These men made up the very best group of general practitioners in the past, devoting more time to their patients and, by and large, having better training. Since quite high percentages of this better income group have elected to go on the panel system, these doctors have suffered as much as 50 per cent reduction in their income. Patients formerly treated on a private basis seem to expect just as much time to be spent with them, involving the various social amenities even though perhaps not necessary for professional reasons.

It is not considered ethical for a doctor to accept extra fees from a patient on his panel, though many former private patients have offered to pay extra

for special attention. When such people find this is not available to them on the panel system, a considerable number will likely return to a private patient status and thus help solve part of this problem.

Under the present plan there seems relatively little incentive for general practitioners to do a better type of work. A tapering capitation fee (perhaps $6 per patient for the first 1,000 on one man's panel) is being discussed a great deal and seems to find favor with the British Medical Association. Perhaps it has certain advantages and would at least make it possible for a physician to handle a smaller number of patients than at present without so seriously reducing his income. Young men desiring to go into general practice are having some difficulties in finding situations open to them, and this is a problem which demands correction. The system provides opportunities for young trainees to receive $2,800 per year working with a general practitioner approved for the purpose; the latter to receive $600 for providing the training. When fully implemented this training plan should have real advantages.

There are no restrictions on prescribing of drugs by general practitioners and they feel this is a very real advance under the new system. Ten or a dozen chemists interviewed at random had no faults to find with the new Service from their standpoint, even though a very high proportion of their business now comes under this heading. Not a single one of those interviewed reported instances of patients presenting a prescription for drugs and asking that cosmetics, etc., be provided instead of the medicine. It is true that many people who would have purchased minor remedies independently now go to their physician for a prescription, since these remedies are available to them under the Service without extra cost and this complicates the physician's work.

Chemists are paid on the basis of the cost of the drugs involved in a given prescription plus a dispensing fee and the cost of containers. In the London area during November, 1948, prescriptions were written under the system at the rate of $0.49 per person in the area; the average cost of the prescription was $0.54 though some of them went as high as $40 to $50 each. Every local council maintains a register of patients in its area filed both alphabetically and by general practitioner responsible for providing service. As yet there is no register set up on a national basis, though this will undoubtedly be necessary eventually.

During the period July to December, 1948, some 360,000 pairs of spectacles were provided in the London area alone. Over 2,000,000 have been provided nationally. Demands for spectacles have been much greater than expected, and there is now a lag of 3 to 4 months in providing spectacles. As this is on a fee for service basis, costs have skyrocketed; being three to four times what was estimated. A patient desiring glasses must secure a note from his general practitioner saying that they are necessary before he may be examined, but this check has not proved as much of a deterrent as was anticipated.

Dental services have also greatly exceeded expectation. Under the old insurance plan where each patient paid half of the cost of dental care, about 8 per cent took advantage of dental services each year. It was estimated that under the new scheme only 10 per cent each year would take advantage of the fully-paid services available, but actually some 20 to 22 per cent are doing so. A fee for service system prevails with fees as high or higher than those formerly charged in private practice. The Ministry of Health realized this was so but apparently felt greater incentives were needed to bring new

men into dentistry because only one-third the number necessary to provide full service for the population is available. Expectant mothers, preschool and school children are supposed to have priority dental service under the plan; this being the responsibility of the local public health authorities, using salaried dentists for the purpose. However, fees under the plan, sometimes being as high as $4,000 per month, have lured many of these salaried dentists into the ranks of practitioners. Fees were computed on the idea that a dentist could conscientiously do only about 33 hours per week of chair-side work. Actually many of them are working 60 to 70 hours per week. It has been found necessary to reduce fees to 50 per cent when they run above a specified minimum. There is little doubt that much more radical adjustments will be needed in the dental field if priorities set up are to be maintained. Obviously, there are not nearly enough dentists to meet the pressing demands of the entire population.

Local public health officers feel they have been severely "let down" under the new scheme, having been deprived of their hospital-operating functions which had become such an important part of their responsibilities in the past 15 to 20 years. Their salaries have not yet been increased as recommended under the Spens Reports, since they come from local authorities which consider recommended salaries disproportionately high compared with other local officials. Few students are applying for admission to public health schools. Even the London School of Hygiene has a greatly reduced number of students, and many others have ceased operations almost entirely. The plan calls for local authorities to provide health centers on the basis of one for each 10,000 to 20,000 of population. These centers would contain not only public health clinics but also offices for private physicians and dentists in which they might see their panel patients and for which they would pay an amount of rent as yet unspecified. Present regulations would prohibit visits of private patients to these health centers. As a matter of fact, no health centers of this type are in operation as yet, and it now appears that there will be years of delay due to rigid restrictions on building. Many feel that temporary quarters should be prepared for use as health centers, but others in authority are insisting that the health center plan be delayed until proper specially constructed buildings can be provided.

Public health laboratory services are more readily available than clinical pathological services, since there is a national system of public health laboratories which grew out of the wartime plan of regional laboratory services. These are available to general practitioners on a rather satisfactory basis.

Division of authority under the health services plan is especially striking in the field of maternity care. Regional hospital boards are responsible for maternity hospital services; local authorities for midwife services and antenatal clinics, and general practitioners may provide home delivery service on a fee basis in addition to receipts from their panel patients. There is some attempt to coördinate this and other types of services by the method of joint employment; a given obstetrician or tuberculosis specialist being paid jointly by the regional hospital board and the local public health authority. This is one type of coördinating mechanism which, it is hoped, will help to unify the service.

One may summarize certain defects which make the British system as presently constituted less than perfect. The administrative structure of operation is, to say the least, unwieldy. Attempts to make the operations democratic have in some cases reduced central authority to such a dangerously low level that proper administration and

budgetary control are proving difficult. Personnel is being drawn off from one branch of the service to another. School dentists are going into practice and public health officers into hospital service. Certainly general practitioners would be wise to attempt to become specialists unless their present lot is improved. Basic science faculties in the medical schools are being depleted because salaries for clinicians are much higher than available to them if they remain as basic science teachers. Facilities and personnel are insufficient to provide all the services which have been promised the people. There are insufficient nurses to staff even the beds presently available. One gathers the definite impression that too much has been attempted in too short a time. Not nearly enough trained administrators are available and little effort is being made to provide additional training. Education of the public seems not to have sufficiently emphasized the shortages although it is evident that the public itself is not surprised at this so far. Many people realize that it may be 10 or 15 years before a really complete service will be available to them. Health centers, basically important to satisfactory operation of the plan, are not yet provided, and there is little evidence that even experimental health centers will become available in the near future. Pilot studies to indicate the extent of demands for services have been inadequate, accounting to a considerable degree for the fact that estimates of costs were much too low. The problem of defining qualifications of specialists is proving difficult though one might have predicted that this would be by no means an easy task.

Too much paper work is being demanded of general practitioners who must sign certificates for disability payments, various types of rations, etc., in rather surprising volume. It is perhaps fair to say that by and large, general practice is being overburdened and that vigorous measures will be required to correct this situation, probably the most serious problem existing at present. Original estimates of costs have proved entirely too low and recently a deficit appropriation of some $240,000,000 additional was requested and granted. It is interesting however, that in the parliamentary debates over this request, while protesting the administrative ineptness of the Labor government the Conservatives stated unequivocally that the health service plan itself was not being opposed since it actually had been originated under Churchill's prime ministership. Even at the present rate of cost, the expenditures per person per year are approximately $30 so that it can scarcely be said that the costs are exorbitant.

There are very definite strengths in the plan which should be emphasized. Universal coverage is now established as a right. The man on the street feels this is a very valuable possession and that abolition of the "means test" has been an extremely worth-while accomplishment. The functional and geographic grouping of hospitals under management committees and the regional hospital boards will unquestionably prove of very great value. Boundaries previously existing under local authority jurisdictions and under the voluntary hospital system have been rubbed out and grouping can now be made on the basis of hospital service areas, which, of course, is much more realistic. Excellent specialist services are being built up and there seems every reason to feel that progress in this direction will be not only rapid but extremely worth while. General practitioners are now able to prescribe any drugs desired and are seeing illnesses in much earlier stages than before. Representatives of organized medicine in Great Britain state that they have been dismayed at the very unfavorable reports being cir-

culated in the United States on the present situation in Great Britain. They welcome the opportunity to point out their approval of the general principles of the plan and to indicate that administrative readjustments required to bring about improvements appear by no means to be impossible of accomplishment.

One may say then, in general, that there are both good and bad features of the British plan as it is now operating. Those in authority recognize the bad features and certainly give every impression that yoeman efforts are being made to iron out the difficulties. No one expects this can be accomplished overnight, but much hard work is being put in by both advisory committees and responsible officials to improve the system as rapidly as possible. Up to the present time the public reaction is favorable on the whole. If progress in bringing about improvements is made at a reasonable rate, it seems probable that public approval will continue.

While the British plan as a whole would not be applicable to all parts of the United States, there are many features from which we can learn a very great deal in planning for improvement in our own national health services.

Outbreak of Jungle Yellow Fever in Panama

According to information released by Fred L. Soper, M.D., Director of the Pan American Sanitary Bureau, Washington, D. C., to the public health departments of the 21 American Republics, several cases of confirmed jungle yellow fever occurred in the last 2 months of 1948 in the vicinity of the town of Pacora, Panama. The cases diagnosed by post-mortem examination are classified epidemiologically as typical jungle yellow fever; 4 of these occurred in workers who were engaged in cutting timber in the forest, and 1 in a person who had spent a week hunting in the same jungle area of Panama.

Dr. Soper, late in January, advised countries having airline communication with Panama that he believed that the jungle yellow fever there does not constitute a danger to other countries through passengers in transit. The cases of the fever were limited to workers in the jungle. He suggested that vaccination against yellow fever be required of passengers whose travel originates in Panama.

The health authorities of Panama, where no clinical case of urban yellow fever has occurred for 50 years, and where until this time no human cases of jungle yellow fever had been diagnosed, recalled some positive protection test discovered in 1941 between the Canal Zone and the Colombian border. In order to prevent the occurrence of urban cases, or cases transmitted by Aedes mosquitoes, the basic measure to be taken is the eradication of Aedes, preferably on a continental basis. According to Dr. Soper, in areas favoring the development of jungle yellow fever, the measure to be recommended is vaccination of all persons residing in those regions. He was of the opinion that there is no danger for persons who are simply in transit through cities without *Aedes aegypti.*

Can Child Accidents Be Prevented in Your Community?

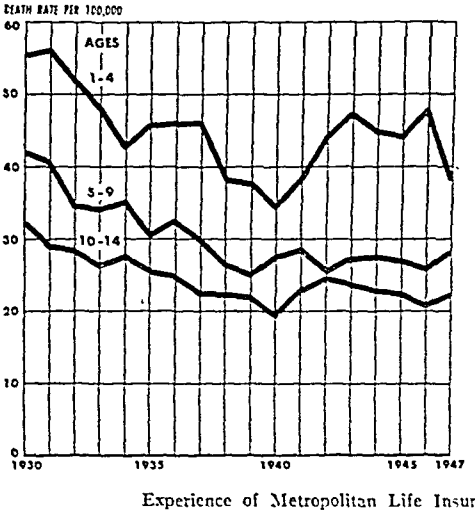
D. B. ARMSTRONG, M.D., F.A.P.H.A., AND W. GRAHAM COLE

Second Vice-President; and Assistant Secretary; Metropolitan Life Insurance Company, New York, N. Y.

THE fact that no immunization procedure could have prevented the accident which resulted in the fatal burning of a 2 year old child who had been playing with matches, in no way lessens the sorrow or anguish of the bereaved parents. The fact that no simple scientific method has been developed which could have prevented the deaths of about 12,000 children aged 1 to 14 who died last year as a result of accidents, in no way lessens the distress and the social and economic losses resulting from these deaths. But these facts do emphasize the responsibility of medical and public health agencies to study, develop, and apply effective measures for the control of mortality and morbidity resulting from accidents.

Although the accident death rate among insured children in the age group 1 through 14 showed a 29 per cent reduction during a recent 15 year period, this decline was not consistent and compares unfavorably with the reduction in child deaths due to disease. As a result, accidents today represent the first cause of death among children and present a major child health problem. While much remains to be learned through research regarding the underlying physical and emotional factors responsible for accidents and involved in accident proneness, still we are far from

FIGURE 1—Fatal Accidents Among Children



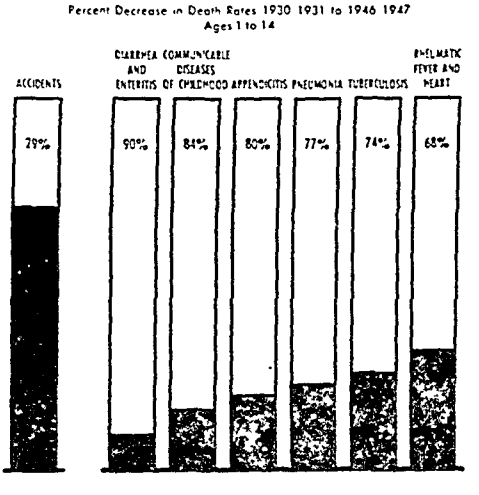


FIGURE 2—Accidents versus Certain Diseases

Experience of Metropolitan Life Insurance Co.—Weekly Industrial Department

utilizing fully our present knowledge as to the prevention and control of accidents.

National Approach to Child Safety

In an effort to stimulate more intensive interest in the subject of child safety, the Metropolitan Life Insurance Company with the cosponsorship of the Children's Bureau of the Federal Security Agency, the American Academy of Pediatrics, and the National Safety Council, has launched a continuous child safety program. It is the distinct purpose of this program—

1. To encourage parents, other adults, and older children responsible for the health and happiness of younger children, to
   a. recognize the accident hazards confronting young children;
   b. provide and maintain safe conditions for the child in the home and at play;
   c. help the child, through example and guidance, to develop safe practices.
2. To encourage public health, medical, and other interested agencies to give added emphasis to child safety in their own programs.

Child Safety—A Community Challenge

The effectiveness of any effort to reduce the frequency and severity of child accidents will in the final analysis depend upon the steps taken by each community throughout the nation to study the child accident problem and to stimulate individual and collective control measures within its area of influence. The seriousness of this problem justifies such community action on an organized and sustained basis. Although local problems may warrant special emphasis and adaptation, child safety activities, where practical, should be integrated into the overall health and safety program of the community.

As a guide to organizations or individuals interested in planning or developing a continuous community child safety program, this article lists the more important studies and activities which warrant consideration. It is recognized that all of these studies and activities may not be appropriate for every community and that additional suggestions may be developed as a result of a study of the local situation. It is hoped, however, that the following may provide a check list to aid in suggesting a practical program for your community.

ORGANIZING YOUR COMMUNITY FOR CHILD SAFETY

Sponsoring or Directing Agency

To be effective a local child safety program must be initiated and sponsored by some agency which accepts, as a major responsibility, the improvement of child health and safety in the community. Accordingly, an opportunity exists for the department of health, the health council, or the safety council, to assume this leadership, either singly or jointly, depending upon which type of leadership in a particular community is in a position to obtain the fullest possible coöperation of other agencies and to produce the most effective results.

An Organization Meeting

In addition to the leadership of the sponsoring agency, a sustained program to control child accidents in a community will require the support and active participation of such official agencies as the board of education, and the police, fire, hospital, building inspection, and park departments; as well as the coöperative efforts of nonofficial agencies having an interest in the conservation of child life. To develop this support and participation, and to discuss plans for a coöperative child safety program, a meeting of representatives of interested official and nonofficial agencies is desirable. Among the nonofficial agencies which might be invited to send representatives to such a meeting may be listed:

County Medical Society
Other Professional Societies, including Medical, Dental, and Nursing
Visiting Nurse Association
Health Organizations
Safety Council or Other Safety Organizations
Social Service Agencies
Youth Organizations (Boy and Girl Scouts, Campfire Girls, 4H Clubs, etc.)
Women's Organizations
Automobile Club
Parent-Teacher Associations
Red Cross Chapter
Service and Luncheon Clubs
Insurance Club
Neighborhood Associations
Patriotic Groups
The Local Press

The invitation to attend this preliminary meeting might be sent by the sponsoring agency, which should develop and arrange for the meeting; or the invitation might well be issued by the mayor in behalf of the sponsoring agency. A serious child accident or a series of child accidents in the community, accidents in nearby communities, or the existence of a particular local hazard to child safety will usually prove an effective motivating influence and might be given as one of the reasons for calling the meeting.

In arranging for this meeting the sponsoring agency should be prepared to present information regarding the child accident experience in the community and to outline, for discussion, some of the possible activities which might be conducted with the active cooperation of local agencies. This initial meeting should prove an excellent educational opportunity for the representatives attending, and the resulting publicity should prove of educational value throughout the community. During the meeting efforts should be exerted to create a continuing child safety committee.

SUGGESTED COMMUNITY ACTIVITIES

An Inventory of Local Organizations

As a preparatory step in planning the local child safety program, an inventory of local agency activities will be very desirable. Such an inventory might be conducted under the auspices of the newly organized child safety committee. Necessary information could be obtained through personal interviews with city officials and organization officers, or by mail questionnaires.

Those taking the inventory should seek and list information regarding the basic interest of the organization as it affects the child accident problem and its present or contemplated child safety activities. The inventory should also indicate the number of employees, members, and volunteers through whom child safety information can be disseminated; the number and type of employees or members who can actively participate by serving on committees, by investigating and analyzing accidents, by conducting surveys of environmental hazards, by preparing materials, by addressing audiences, and by handling necessary clerical work.

Obtaining Facts Regarding Child Accidents

Factual information regarding the frequency, types, and causes of child accidents in the community is essential to the development of an effective program. Such data are also necessary to the preparation of essential educational and publicity material. The collection and analysis of such data can in themselves serve as an effective educational device.

Data regarding the occurrence of fatal accidents to children are usually obtainable from the records of the local health and police departments. A follow-up of these records by a detailed questionnaire submitted to and filled in by the reporting physician (a plan followed by the Kansas State Department of Health and by the Nassau County, New York, Department of Health), or by personal interviews with members of the injured child's family, is desirable.

Programs based entirely on fatal accident data will fail to include many important causes of permanent and temporarily disabling injuries. Through the coöperation of physicians, visiting nurses, hospital and police authorities, case histories and other data regarding nonfatal injuries to children may be obtained. Questionnaires distributed through the schools and house-to-house interviews by trained interviewers have been used to collect such data.

Factual data regarding child accidents should include the age and sex of the child; the area of the community where the child lives and was injured; the place of the accident, i.e., home, school, playground, street, at work, or other specified location; the kind of accident; the nature and seriousness of the injury; the unsafe environmental conditions or practices involved in the accident. Where possible to obtain, information regarding the underlying causes of individual accidental injuries —such as contributing physical impairment of the injured, and the psychological, emotional, and sociological factors involved—is a valuable diagnostic aid.

Survey of Physical Conditions Affecting Child Safety

Information regarding environmental physical conditions which may affect child safety is essential in order that proper corrective action may be planned and undertaken. The analysis of accident data will disclose the location of some hazardous situations; observation and investigation will be necessary in order to determine other such situations, and to plan and recommend the proper remedial measures.

Among the areas justifying study in most communities to determine child accident hazards, may be included—

The Home and Its Environs

Unsafe physical conditions in and around homes are important contributing causes of child as well as adult accidents. The correction of home hazards, particularly as they are affected by child growth and development, should accordingly be considered as an essential phase of a child accident prevention program.

Although local regulations in some communities may permit fire or sanitary inspectors to enter private homes for the purpose of checking compliance with their respective local requirements, the official inspection of homes for unsafe conditions is seldom, if ever, provided for by law. Fire and sanitary inspectors, however, can render an effective community service by calling attention to unsafe conditions, particularly those affecting child safety, as noted during their authorized inspections.

Physicians and public health nurses, because of their close contact with parents, are frequently in a position to encourage the correction of unsafe conditions, particularly those affecting children.

Home inspection check lists have been used in a number of communities to encourage voluntary home inspection. These check lists have been distributed to children in the schools to take home for their parents or other adults to fill out and to return by the children.

The School Premises

Unsafe conditions on the school premises may not only be the cause of injury to children, but also may tend to offset the value of otherwise effective safety education. Preliminary inspection of school premises may be made through the coöperation of the local school and building inspection authorities. Additional assistance can usually be obtained from the local engineers or inspectors of casualty insurance companies.

Periodic inspections should be made by the school custodian. Properly supervised inspections by pupil safety com-

mittees will aid in finding unsafe conditions and will also serve as an effective teaching device.

In any inspection, special attention should be given to laboratories, shops, kitchens, and other work areas used for instruction purposes, and to play and recreational areas.

Playground and Public Recreational Areas

A periodic check of playground and other recreational equipment and the facilities provided for the protection of children at swimming pools and bathing beaches is usually warranted as part of the community child safety program.

Traffic Conditions

Frequent observations of traffic conditions on streets adjacent to schools and playgrounds, made by members of the parent-teachers association, neighborhood association, and automobile club, in coöperation with police authorities, will aid in determining unsafe conditions and in suggesting remedies. The use of schoolboy patrols, the installation of proper school stop signs, and the designation of play streets may effectively supplement the activities of the police at these locations.

The determination of safest routes for children to use in going to and from various residential areas and their respective schools, has proved a valuable means of controlling child accidents on the street and has also been used as an effective upper-grade safety educational project.

Press Publicity

Frequent references to the local child safety program and facts concerning the child accident problem of the community printed in the local press, will prove a valuable means of stimulating widespread interest and of encouraging additional activities. Such publicity might well include news items regarding various activites of the child safety program, editoral comments, signed articles or endorsement (by prominent local people), weekly analyses of local child accidents, human interest stories of child accidents, question and answer contests, photographs, cartoons, etc.

Radio

The local radio station can contribute to the child safety campaign by utilizing national program material dealing with child safety, and by arranging for special programs over the local station. These special programs might include the broadcasting of local addresses on child safety, the presentation of locally developed skits, spot announcements, interviews with prominent citizens interested in child safety, etc.

Safety Education in Schools

A continuous and effective safety program, conducted as a part of the regular school curriculum, will prove one of the most important phases of the local child safety activities. Such a program should seek to develop safe practices on the part of students and to encourage a sense of responsibility of the older-age children for the safety of the younger ones.

The integration of safety material into the health educational activities of the schools and into permanent regular curricular subjects, has usually proved most effective, particularly when proper consideration has been given to child growth and development. To accomplish these aims teachers should be supplied with proper teaching aids including current data on the local child accident situation.

The organization of school safety councils or committees among the pupils to investigate accidents, develop school safety rules, organize school safety patrols, and suggest safe routes to and from school, has proved of value in many schools. Courses in vocational training provide outstanding opportuni-

ties to incorporate child safety education as a means of protecting the child at school and of developing future safe workers. The introduction of driver training courses in the upper classes of the high school provides an additional direct means of child safety education.

Supplemental Safety Education

Red Cross chapters in many communities are in a position, through their First Aid and Accident Prevention activities, to present home safety courses for adults and junior safety courses for organized groups of children.

Meetings and Addresses

The effectiveness of the local child safety program can always be increased through the use of the spoken word. The regular meetings of local civic, service, patriotic, fraternal, neighborhood, parents, and women's groups provide an opportunity to introduce the child safety theme through scheduled addresses by competent individuals interested in the various phases of the problem. Arrangements can also frequently be made to have speakers appear before religious bodies, or material can be furnished to the religious leaders for their own use. Skits and demonstrations on child safety can be used effectively at these meetings.

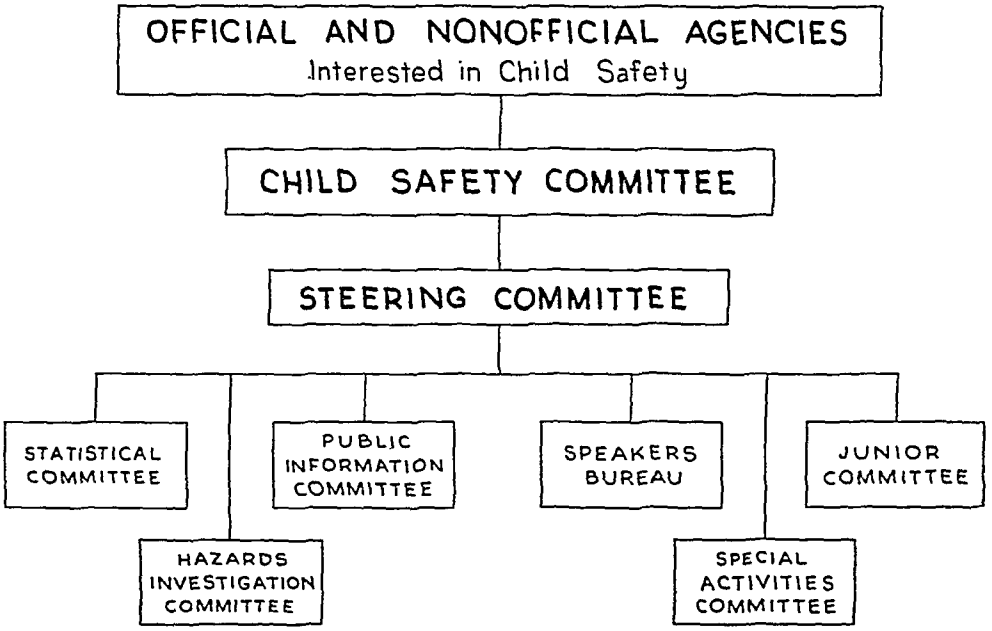
To take full advantage of this method of reaching the public, a speakers bureau may be desirable.

Exhibits and Demonstrations

Exhibits of safe toys, safe nursery equipment, and other materials pertaining to child safety usually provide an effective means of instructing the public and of stimulating widespread comunity interest. Such exhibits may be used at organization meetings and may be displayed in store windows or other public places where they will be seen by large groups. Local merchants may be interested in developing and arranging for the display of such exhibit material. To stimulate community-wide interest in this project a contest might be conducted to determine the most effective and constructive exhibit displayed during a specified period. For example, a safe toy exhibit displayed in various store windows during the first week or two of the Christmas buying season, may prove of considerable value.

Distribution of Material

Effective material, booklets, leaflets, hand dodgers, etc., pertaining to child safety, distributed directly to homes, will aid materially in informing the public of the seriousness of the child accident problem and of means of preventing such accidents. In addition to material of this nature, which may be obtained from national or state agencies, locally prepared material can be used effectively. Various methods have been used for distributing material. For example, it has been furnished to children in the schools to take home to their parents; it has been enclosed with the bills of public service organizations, stores, etc.; and has been given house-to-house distribution by local representatives of insurance companies. It has also been used effectively as a teaching device by public health nurses.



SUGGESTED PLAN OF ORGANIZATION FOR A COMMUNITY CHILD SAFETY PROGRAM

In order to plan and conduct an effective community-wide child safety program coördinating the activities of interested agencies, a definite plan of approach is desirable. The following committee structure is suggested for consideration and adaptation to the needs of your community.

CHILD SAFETY COMMITTEE

Membership — Appointed representatives of each interested and coöperating agency (see list

SUGGESTED ORGANIZATION CHART

of official and nonofficial agencies in the early part of this paper).

Functions—

To study the local child accident problem.

To plan and carry out an effective preventive program by coördinating the activities of coöperating agencies.

To appoint and guide necessary special committees or subcommittees to carry out effectively the coördinated child safety program.

EXECUTIVE OR STEERING COMMITTEE

Membership—Chairman of each special committee or subcommittee and such additional members as may seem desirable.

Functions—

To conduct an inventory of coöperating agencies (see early part of this paper).

To develop the overall policy to be followed in the child safety program.

To review the reports and recommendations of subcommittees before presentation to the Child Safety Committee for adoption and action.

To represent the Child Safety Committee in the interim between meetings.

STATISTICAL OR FACT FINDING COMMITTEE

Functions—

To collect and analyze available data pertaining to the child accident experience of the community.

To plan and conduct such studies, surveys, house-to-house interviews, etc., as may be necessary to obtain statistical facts and case examples of nonfatal disabling accidents to children.

To interpret factual data for the use of the Public Information Committee and for the use of coöperating agencies in planning their preventive activities.

HAZARD INVESTIGATION COMMITTEE

Functions—

To develop a continuing plan for the investigation and reporting of physical conditions affecting child safety in the community.

To organize and train volunteer workers, representatives of coördinating organizations, and other interested individuals, to make investigations and offer recommendations.

To develop an effective method of following up and obtaining action on recommendations resulting from investigations.

PUBLIC INFORMATION COMMITTEE

Functions—

To collect and review available publications on child safety including pertinent material on child growth and development.

To prepare and furnish material pertaining

particularly to the local child safety problem, to the local press, local radio stations, speakers bureau, school authorities, and other coöperating agencies.

To plan and arrange for the conduct of child safety training courses for professional leaders, parents, and older-age children.

To arrange for the proper local distribution of effective child safety material.

SPEAKERS BUREAU

Functions—

To prepare a list of individuals who are willing and capable of accepting speaking assignments.

To secure engagements for these speakers.

To furnish material provided by the Public Information Committee, for the use of the speakers.

SPECIAL ACTIVITIES COMMITTEE

Functions—

To plan and develop such special activities as may be deemed desirable in order effectively to keep the child safety problem before the public.

JUNIOR COMMITTEE

Membership — Representatives of the local Youth Council and of school student councils. If deemed desirable two junior committees might be organized—one on the grade school level and the other on the high school level.

Functions—

To plan, organize, and conduct youth and student participation in such pertinent activities of the Child Safety Committee as the investigation of accidents and child hazards, the development of school safety councils and patrols, the preparation of material for the Public Information Committee, and the acceptance of speaking assignments as requested by the Speakers Bureau.

SUMMARY

At the present time, accidents are the first cause of child deaths and an outstanding cause of child morbidity in this country. The reduction of child accidents during the past fifteen years has by no means approached the marked reduction of child mortality and morbidity due to disease. Accordingly, child accidents represent a major child health problem requiring further study and research and the more effective utilization of present knowledge regarding prevention and control.

The seriousness of the child accident problem presents a definite challenge to responsible public health agencies for the initiation and conduct of well organized community programs planned to coördinate the activities of all local official and nonofficial agencies interested in child safety.

Chronic Disease

The Chronic Disease Study of the California Department of Public Health *

WILTON L. HALVERSON, M.D., DR.P.H., F.A.P.H.A.,
LESTER BRESLOW, M.D., F.A.P.H.A., AND
MALCOLM H. MERRILL, M.D., F.A.P.H.A.

State Director of Public Health; Chief, Chronic Disease Service; and Deputy Director, State Department of Health, San Francisco, Calif.

PUBLIC health agencies have only recently begun to face the problem of chronic disease. The need for action has been amply demonstrated. The facts concerning the aging of the population and its influence on chronic disease mortality and morbidity are all well known. These facts offer no surprises to welfare agencies, hospitals, voluntary health agencies, physicians, nurses, and the millions of families who cannot ignore the day-to-day problems of chronic disease.

Viewed historically, it is appropriate here in Boston to note that the first significant attack on this problem by a state health department was that launched in Massachusetts in 1926. Since that time, other states have entered this field but for the most part their activities have been limited to cancer control.

Recent events provide concrete evidence of growing public health concern with the problem of chronic disease. First, the American Public Health Association, the American Medical Association, the American Hospital Association, and the American Public Welfare Association, working together in 1947, developed and published a basic, joint statement of principles entitled "Planning for the Chronically Ill."[1] It is noteworthy that the subject of chronic disease brought these four groups into a coöperative working relationship for the first time.

A second evidence of public concern about chronic diseases is the emphasis given this subject at the recent National Health Assembly. A special section was devoted to this topic. In addition, the section devoted to Local Health Units listed chronic disease control as one of the seven basic activities of health departments.

A third event, also of primary significance, is the cognizance of the problem taken by Congress through passage of the act establishing the National Cancer Institute and the National Heart Act with the appropriation of funds to implement these acts.

These events leave no doubt as to the growing interest in the challenging field of chronic disease.

It was a realization of this growing interest and of the increasing magnitude of the problem involved that was the genesis of the chronic disease investigation in California.

INITIATION OF CANCER CONTROL PROGRAM

In August, 1946, the California State

* Presented at a Joint Session of the Epidemiology, Health Officers, and Statistics Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

Department of Public Health initiated a cancer control program through the use of federally allotted funds. Responsibility for this activity was placed, not in a cancer control unit, but rather in a newly created Chronic Disease Service. This was done in recognition of the fact that cancer is but one of many chronic diseases which may be subject to the same general public health approach. It was realized that the organizational pattern developed for cancer control may also be useful in programs for heart disease, diabetes, and other chronic diseases. Health departments have developed techniques and specialized personnel in such fields as statistics, nursing, health education, laboratory, and administration. Once used principally for communicable disease control and then extended to other areas, these techniques and personnel are now being mobilized for cancer control. They are equally applicable to the other chronic diseases.

LEGISLATIVE RESOLUTION

As indicated above, the program in California was launched with federal cancer control funds. In order to determine what the state's interest should be in the broad field of chronic diseases, the California Legislature, in June, 1947, passed a Resolution directing the Department of Public Health to "investigate the problems involved in the reduction of deaths and disability from cancer and other chronic diseases." The department was directed to "report to the 1949 general session of the Legislature the results of its investigation and make recommendations as to a program for the reduction of such deaths and disabilities and the costs thereof."

ADVISORY COMMITTEE

To guide the department in this chronic disease investigation, an Advisory Committee was appointed by the State Director of Public Health. The committee includes prominent representatives from professional fields, such as the Chairman of the Council of the California Medical Association, the Administrator of Alameda County Hospitals, the Medical Director of the Los Angeles County Department of Charities, the Director of the State Department of Social Welfare, the Medical Director of the Pacific Branch of the Metropolitan Life Insurance Company, the Health Officer of a county health department, an official of the California Osteopathic Association, and the Dean of the School of Public Health of the University of California. Community interests, such as business, farm, labor, local government, parent-teachers associations, and voluntary health and welfare groups are likewise well represented.

To date, the committee has met five times. The first meeting was in December, 1947, and subsequent meetings were held in March, June, September, and November of this year. The committee will meet again early in December to review a draft of the report to the Legislature. This will include such recommendations as may be decided upon by the committee.

The committee has demonstrated a keen interest in the problem. It has called for at least six meetings, rather than the three originally suggested. Attendance at the day-long meetings has been excellent. In addition to formulating general policies for the investigation, the committee has plunged into many important detailed aspects of the work. For example, it prepared a list of diseases to be included in morbidity and mortality studies and it examined the particulars of the state rehabilitation program and other present programs relating to chronic disease. Individual committee members worked with the Chronic Disease Service staff in developing schedules and questionnaires used in the investigation. At the committee's suggestion, the task of preparing recommendations for inclusion in the report

to the Legislature has been parcelled out to individual committee members who will submit drafts to the committee as a whole.

NATURE OF STUDY

The chronic disease investigation is proceeding along two fronts. On one hand, consideration is being given to the problems more or less common to all chronic illness, such as hospitalization, rehabilitation, and custodial, nursing home, and home care services. On the other hand, technical advisory groups, auxiliary to the general advisory committee, are directing special attention to the problems relating to particular diseases, such as cancer, heart disease, diabetes, alcoholism, rheumatism, and dental disease.

An attempt has been made to secure information in the following general fields:

1. To obtain an estimate of the problem as determined from a study of morbidity, mortality, and other data.
2. To secure information on the needs, particularly of services and facilities, for such items as health promotion, prevention of diseases, treatment, rehabilitation, and research.
3. To obtain an estimate of resources presently available.
4. To arrive at recommendations concerning action to be taken.
5. An estimate of the costs.

The methods of the investigation have included a study of pertinent comparable investigations carried out in California and elsewhere, demographic studies, securing of expert opinion from a wide variety of individuals and agencies involved in this field, an intensive review of all present services and facilities for the care of the chronically ill, and, finally, detailed studies in certain areas by technical advisory groups.

A problem confronting all chronic disease studies and investigations is the lack of current data on chronic disease morbidity. In previous studies, the National Health Survey data and ratios have been the principal source of information. The National Health Survey is now twelve years old, and in certain other respects not entirely satisfactory.

For the present investigation, current morbidity data have been available from the California Disability Insurance Program. Approximately three million employed persons are eligible for benefits under this program which compensates, in part, for wage loss due to non-occupational illness. Diagnostic information, available from physicians' statements on claim forms, can be related to demographic characteristics of the claimants as well as to the duration and amount of benefits paid. It is of interest to note, for example, that of the $15,000,000 paid out in benefits during 1947, the first year of operation, approximately one-half was paid for chronic diseases.

Although disability insurance data have proved valuable, obviously they do not give the complete picture of chronic disease morbidity. These data pertain only to illness which occurs in a limited section of the population, and the information is further limited by administrative and legal features of the program. In order to obtain more adequate current morbidity data, that is, data applicable to the general population, consideration is being given to other sources within the state.

We have also been fortunate in having available both the data and the recommendations of the California Hospital Survey completed in 1947. This survey is of particular significance to the present investigation because it presents recent information, thinking, and planning on chronic disease hospital facilities not as an isolated problem, but rather as part of the overall problem of providing adequate hospitals and related facilities in California.

The Joint Statement on "Planning for the Chronically Ill," the statement drafted by the four national organizations last year, has also been helpful.

The Joint Statement was used by the Advisory Committee as a guide in planning the investigation; and it was also used in designing a schedule for a special survey of facilities and services for chronically ill welfare clients in sixteen California counties.

A somewhat different use of the Joint Statement was made in the course of obtaining expert opinion during the investigation. Letter questionnaires were sent to presidents of county medical societies, county welfare directors, public and private hospital administrators, local health officers, executives of voluntary health and welfare agencies, presidents of local osteopathic associations, and county grand jury foremen. The questionnaires, prepared in consultation with appropriate state organizations, were accompanied by copies of the Joint Statement. In this manner, over 500 copies were distributed to persons whose positions make them particularly important in the development of a chronic disease program. By the use of the Joint Statement, however, the Advisory Committee has made it clear that it feels in no way obligated to accept all or any of the broad principles therein enunciated. The committee plans to arrive at its own conclusions on the basis of the findings of the investigation.

The Disability Insurance data, the California Hospital Survey data and recommendations, and the Joint Statement have all been helpful. Of especial importance, however, has been the aid of technical advisory groups for the specific chronic diseases, particularly cancer, heart disease, diabetes, and alcoholism. The Cancer Commission of the California Medical Association, which has made extensive contributions to cancer control in the state over a 17 year period, agreed to prepare a report in its sphere. Likewise, the Heart Advisory Committee of the California Tuberculosis and Health Association is serving as a technical advisory group in its field. With respect to diabetes, in the absence of a state organization, individual members of the American Diabetes Association were consulted and assisted in developing this section of the report. When alcoholism was proposed as a disease deserving of specific attention, the California Medical Association appointed a special committee on the subject.

Members of the medical profession have been devoting many long evenings and week-ends to the difficult problems arising in the fields of their particular clinical interest. Each of the technical advisory groups is defining the objectives of a program, suggesting methods of attaining these objectives, and making specific recommendations on program content and method. These recommendations, in report form, are being submitted to the general advisory committee for incorporation, in such form as the general committee may designate, into the report to the Legislature.

Close working relationships established between these technical groups and the State Health Department staff have proved highly beneficial. These relationships, exceedingly useful during the investigation, offer great possibilities for effective guidance and coöperation in any program which may emerge.

Before concluding this statement, it should be pointed out that while these investigations are under way, the Chronic Disease Service has been gradually working into an operating program. Main emphasis thus far has been on cancer. This control program is being developed in coöperation with the Cancer Commission of the California Medical Association and the California Division of the American Cancer Society. As part of this program, a Tumor Registry has been set up. Hospitals, having in total 33 per cent of the general hospital beds in the state, are submitting cancer case reports to the Registry. Since its inception in 1947, over 20,000 case reports have been received. Follow-up of these

cases is being done by the reporting hospitals, and death clearance is carried on by the Vital Statistics Section of the State Department of Public Health.

Professional education has constituted another phase of the cancer control program. Teams of cancer experts from the medical centers in the state have conducted a number of symposia for physicians in the non-metropolitan areas of the state. A film demonstrating the proper method of examining the breast for cancer was produced and is now being shown. Development of the cytologic technique for cancer detection was stimulated in California, at first, through the training of physicians in eastern centers. This year, assistance is being given to a training center for physicians and technicians within the state.

In addition to these educational measures, surveys of facilities and services for cancer control have been carried out in coöperation with county medical societies. These have been completed for most of the larger counties, and work is now progressing into the smaller counties.

As would be expected, the Chronic Disease Service is keenly interested in the development and use of methods and techniques for early detection of any of the chronic diseases. In this connection, there is special significance in a recent multiphasic survey conducted in San Jose, Calif., by the Santa Clara County Medical Society, the San Jose City Health Department, and the State Department of Public Health. Although the details and results of this survey will be reported elsewhere, the objectives and approach will be of interest to this audience. The survey was set up to determine the feasibility of combining some of our well established public health screening programs with the newer techniques being developed for the chronic diseases. Instead of screening for a single disease entity, a battery of tests was arranged to screen for a number of diseases. The battery included, in part, miniature chest x-rays, which were read specifically for cardiac abnormality as well as for pulmonary pathology, blood and urine tests for diabetes, and a serologic test for syphilis.

SUMMARY

In summary, this paper has attempted to describe the activities of the California State Department of Public Health in the field of the chronic diseases.

In 1946, a cancer control program, initiated with the use of federally allocated funds, was set up in a newly created unit designated as the Chronic Disease Service. In 1947, the Legislature directed the department to conduct a chronic disease investigation. In carrying on this investigation, the department has been fortunate in having available the current morbidity data from the State Disability Insurance Program, the data and recommendations from the recent California Hospital Survey, the Joint Statement on "Planning for the Chronically Ill," and of even more fundamental importance, the services and active interest of a general advisory committee and of several technical advisory groups.

Chronic Disease

Chronic Disease as an Industrial Hygiene Problem *

CLARENCE SELBY, M.D., F.A.P.H.A.
Medical Consultant, General Motors Corporation, Detroit, Mich.

THIS paper reports briefly on the use of vital statistics in industrial health administration and practice. Medical programs in industrial establishments vary in their natures and extent, depending upon the motive of the employers, the wishes of the employees, and the influence of the physicians in charge of their medical programs. In some, surgery predominates (the care of compensable injuries); in others, medical care is outstanding; and in still others, the objective is protection of employee health.

Industrial medical programs of the last mentioned kind are sometimes known as health maintenance programs, occupational or industrial health, industrial hygiene, and occasionally occupational hygiene or medicine. They are becoming increasingly useful to industry and society because they help the employed people to preserve their health, and as a consequence of their growing importance, physicians skilled in this kind of industrial practice are coming to be recognized as specialists. Industrial medicine of this type is really preventive medicine, or, if you prefer, public health, and plant physicians who follow such practices are regarded as the health officers of the plants in which they serve.

It is the health maintenance type of industrial practice that records and studies vital statistics of the employees; and fortunate indeed is the industrial doctor who has such statistical information regularly available.

Industrial vital statistics should include death rates and non-occupational disability rates of the plant population, as well as the information on occupational injuries and diseases which doctors usually collect. It is assumed, of course, that statistics of occupational diseases and injuries are at all times carefully gathered and studied, even though relatively of small consequence compared with the non-occupational sicknesses. Even disability rates from the non-occupational injuries far exceed those of the occupational. In other words, the employed people of the United States are much safer in their places of employment than they are elsewhere, and their non-occupational sickness rates are far in excess of those of the occupational diseases.

In some industries the disability rates on occupational diseases are now as low as 6 minutes per employee per year; while non-occupational sickness rates may be as low as 5 days per employee per year. It is, therefore, clearly evident that regardless of progress, the important industrial health problem is, in

(The above rates exclude disabilities lasting less than a week.)

Respiratory includes tuberculosis of respiratory system, asthma, and hay fever
Cardiovascular-Renal includes pericarditis, endocarditis, organic heart diseases angina pectoris tachycardia, aneurysm, embolism, phlebitis, varicosities, and nephritis
Genitourinary includes nephrolithiasis and pyelitis
Organs of Movement includes chronic rheumatism, myalgia, and neuritis
Nervous System includes neurasthenia, paralysis, cerebral apoplexy meningitis, insanity, and herpes zoster
Assimilative includes anemia and diabetes

reality, a public health problem and not an industrial one.

Industry has a great deal at stake in the health of the employees, and for that reason modern industrial medicine is allied with public health and it uses public health methods. The Corporation with which the writer is associated collects vital statistics currently, and makes monthly and annual studies of the causes of death, as well as sickness disabilities in its employees. As the employees are well distributed throughout the United States, the statistics can be regarded as fairly representative of people employed generally in the mechanical trades. While the health maintenance program of this Corporation follows conventional procedures, certain of its special disease control functions vary from year to year in accordance with the experience and trends which have featured each previous year.

For example: When disabilities from pulmonary tuberculosis, appendicitis, and pneumonia were high, special efforts were made to assist employees in the prevention and control of those diseases. During the war, to use another example, special venereal disease programs were set up. In short, using the language of industry, the medical de-

partment engineers a new industrial health model each year, and the specifications of each are based on the previous year's experience as shown in the vital statistical studies.

The procedure is simple, but it is logical and effective. To illustrate: Tables 1 and 2 show the chronic non-occupational disabilities occurring in 186,000 male and 34,000 female employees respectively during the calendar year of 1947.

Strangely, and perhaps unexpectedly, the most important source of chronic disability last year among males was in diseases of the organs of movement, such as joints, bones, muscles, and nerves. They included chronic rheumatisms, myalgia, arthritis, and neuritis.

As shown in Table 3, which records the death rates of approximately 300,000 male and female employees, diseases of the organs of movement are not causes of death, only of impairment and disability. That finding is significant and the conclusion is obvious. The industrial medical program should give special consideration to the prevention and control of the rheumatisms and other diseases affecting the organs of movement. These take priority, and all examinations, consultations, and health education give special attention to them.

Scanning Tables 1 and 2 further, the industrial physician is impressed by the prevalence of diseases of the nervous system in women, the ratio being five times that of the men. This is an observation of great significance and important in the determination of the medical program. The industrial doctor is also impressed by the high rates of diseases of the heart, blood vessels, and kidneys in both sexes.

The present industrial health maintenance program is, therefore, engineered to assist management in furnishing healthful working conditions and environments, which is a routine year-in and year-out function of the industrial medical departments, and to help the employees in their efforts to prevent and control chronic degenerative diseases, giving particular attention to the rheumatisms and diseases of the nervous and vascular systems.

Scanning the mortality table (Table 3) which contains data from an industrial population of 300,000 people, one notes that the long-range industrial medical program must give attention to cancer as well as the other disability sources mentioned above.

It is of passing interest to observe that the more we study industrial vital statistics, the more we realize the importance of gerontology and geriatrics. But those subjects are beyond the limited purview of this brief paper.

The modern industrial health maintenance program is organized to furnish the following services:

1. Diagnosis and treatment of all *occupational* injuries or illnesses
2. Temporary care of minor non-occupational

ailments and First Aid in non-occupational emergencies
3. Consultations for necessary medical advice
4. Assistance in the diagnosis and control of tuberculosis and other communicable diseases
5. Examination at the time of employment to aid in proper placement on a job for which the employee is best suited
6. Periodic examinations to aid in the maintenance of the employee's health
7. Granting of sick leaves and approval of return to work
8. Plant inspection and control of possible sources of occupational diseases

These, however, vary from year to year in accordance with results and trends shown by studies of industrial vital statistics.

The Participation of Official Health Departments and Coöperating Voluntary Agencies in a National Program for Home Safety*

The American Public Health Association, the U. S. Public Health Service, and other national health agencies to a total of 37 are members of the Home Safety Conference. The following declaration bearing on the participation of health departments and voluntary agencies as adopted by the Home Conference of the National Safety Council is reprinted herewith.

Accidents in the home are responsible for more deaths and injuries than any other accident classification; more than 30,000 people are killed and more than 5,000,000 injured every year in home accidents.

In considering what to do about this enormous accident toll, the Home Conference is well aware of the recent policy statement by the National Safety Council's Board of Directors, pointing out that "the size and complexity of the accident problem require the acceptance of responsibility not alone by individuals but by organizations and agencies, such as are found in agriculture, transportation, business and industry, civic enterprises, health and welfare work, education, government and labor."

The particular role of government agencies in safety has been well established for many years in some fields. For example, police, motor vehicle, and highway departments are recognized as having primary responsibility for traffic safety. Likewise, industrial and labor departments administer laws for industrial safety.

The last few years have seen an aroused interest in safety on the part of official health departments, on the community, state, and national level. While this interest has by no means been exclusively in matters of home safety, home accident prevention has been by far the most important target of health department work in the field of safety.

The Home Conference views this increasing safety interest on the part of health departments with appreciation and enthusiasm. In particular, the Conference wishes to recognize the very important part which official health agencies can play in the promotion of home safety. Public health departments have developed over the years many close contacts with the homes of our citizens. In the control of communicable diseases, public nursing services, general health education, and many other activities, health departments have developed and maintained channels of contact between health departments and the home.

With these facts in mind, we call upon official health departments throughout the country to expand their efforts in the field of home safety. In doing so we have no thought that these departments will or should be uninterested in other phases of safety, nor do we have any thought of discouraging the interest of any other governmental unit or of any non-governmental safety agency in home accident prevention.

In calling for an expanded program of home safety by health departments we wish to emphasize our belief that the greatest success can be achieved only through the cooperative and coördinated efforts of official agencies and of voluntary safety and health agencies working together. The Home Conference, we believe, offers an ideal medium for achieving such coördination and coöperation in home accident prevention.

* Adopted by Executive Committee of Home Safety Conference, January 26, 1949. Approved by the Board of Directors of the National Safety Council, March 29, 1949.

Chronic Disease

The Use of Statistics in Cancer Control Programs *

HAROLD F. DORN, PH.D., F.A.P.H.A.

Statistician, National Cancer Institute, U. S. Public Health Service, Washington, D. C.

THE words "cancer control" imply that an effort is to be made to prevent any increase in the incidence of cancer, to attempt to lower the present incidence, and to improve methods of therapy to the extent that persons who develop cancer rarely will be disabled or die from its effects. Furthermore, the word "control" implies ability to measure the success or failure of these efforts, since without quantitative measurements there can be no certainty that control is being achieved. Statistical studies and investigations, thus, are an essential part of a cancer control program.

Statistical indices should be devised to measure the success of every element of a cancer control program whether it be detection centers, diagnostic clinics, case finding, use of public health nurses, development of diagnostic tests, lay education or professional education. The development of a quantitative measure of achievement should be an integral part of the initiation of any new aspect of the cancer control program; otherwise we cannot determine the extent to which it is contributing to the control of cancer. It is obviously impractical to discuss in detail at this time the possible applications of statistics to every part of a cancer control program. Consequently this discussion will be limited to one or two applications of statistics and will attempt to show how these applications can be used to determine the success of control measures.

In developing and organizing a cancer control program, information concerning the incidence and prevalence of malignant neoplasms and the characteristics of people who contract cancer is essential. These data not only describe the magnitude of the existing problem but also provide a basis for assessing the future success of the program. Mortality statistics alone are not satisfactory for this purpose. Such data indicate the failure of present efforts to cure cancer once it has occurred. They do not adequately measure success either in preventing cancer or in curing existing cases of disease. As methods of prevention and cure of cancer improve, mortality records will become less and less useful as a sole measure of success, since they do not reveal which elements of the control program are contributing most substantially to the decline in mortality. This does not mean that mortality data are of little or no value and that their analysis should be neglected. On the contrary, they provide a large amount of useful information. But a more direct measure of the success of cancer control activities is needed, since these ac-

* Presented at a Joint Session of the Epidemiology, Health Officers, and Vital Statistics Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

tivities are directed toward cancer in the living population.

This realization has stimulated interest in the reporting of cancer cases and establishment of cancer registers. About one-half of the states have made cancer reportable by law or regulation. A few additional states are attempting to obtain morbidity reports on a voluntary basis. Some states have patterned cancer morbidity reporting after that for communicable diseases. A single report is obtained after diagnosis of a case of cancer; no additional information about the subsequent history of the case is received except that the fact of death may be established by checking case reports with death certificates. Other states have patterned cancer morbidity reporting after tumor registries such as those which are maintained by the American College of Surgeons and the Army Institute of Pathology. Before discussing the merits of these two systems, I would like to set forth the objectives of morbidity reporting and the role it can play in cancer control.

One of the objectives of statistical reporting of morbidity from cancer is to obtain information concerning living cases of cancer at the earliest possible stage in the development of the disease. This information should include among other items the total number of new cases diagnosed, the geographic distribution of these cases, their demographic characteristics such as age, sex, color, and marital status, the type of neoplasm, the primary site, the method of diagnosis, the stage of the disease at the time of diagnosis and identification of who made the diagnosis and provided treatment. Since many cancer cases are seen by more than one physician or hospital, the name and address of each case is essential not only to eliminate duplicate reports but also to obtain subsequent information concerning the outcome of therapy.

I do not believe that a routine morbidity reporting system should attempt to include more than a very few items beyond those mentioned above. Experience has demonstrated that extensive or complicated forms will not be accurately completed, and that resistance to reporting increases rapidly as forms become increasingly complicated. A routine reporting system is not the proper means for the collection of detailed data for the epidemiological study of human cancer although it can provide the basis for the selection of a representative sample of cases for intensive investigation of specific problems.

While the gross number of reported cases is of some interest, the full value of morbidity statistics can be obtained only by relating them to the population from which they are drawn, through the computation of rates per unit of population. To obtain reliable conclusions concerning the incidence and prevalence of cancer, morbidity reports must either include all cases, or a representative sample of all cases, diagnosed in a population of known size and composition. The purpose of morbidity reporting is defeated by incomplete or inaccurate reports.

To achieve completeness, the reporting system should cover all medical facilities, physicians, pathologists, radiologists, hospitals and clinics. Although an increasing proportion of cancer cases undoubtedly are admitted to a hospital or clinic at some time during the course of the disease, a significant number, in some areas as many as one-fifth of all cases, are treated exclusively in physicians' offices. Consequently hospital cases are not only an incomplete count of all cases but they also may be unrepresentative with respect to type of neoplasm, primary site, and possibly other factors.

Cancer morbidity reporting is incomplete if it provides only for a single report on a case. In order to evaluate therapy, follow-up reports should be ob-

tained for an indefinite period of years subsequent to treatment. The standard period for follow-up is 5 years; nearly all "cure rates" are based on 5 year "cures." Incidentally most of these are survival rates and not cure rates as they are usually called. I believe that it is unwise to limit follow-up to 5 years after treatment. A case of cancer is not cured until the possibility of the recurrence of the disease is negligible. The period of time necessary to establish this fact probably varies with the type of neoplasm, primary site, method of treatment, and other factors. Cases should be followed until their probability of dying is no greater than that of persons who have never had cancer, whether this period of time be 5, 10, 15 or an indefinite number of years.

The purposeful collection at regular intervals of information about cancer cases can be accomplished by the establishment of a cancer register. As used here, the term, cancer register, means the entire file of information concerning cancer cases, beginning with the initial report and continuing with supplementary information purposefully collected at regular intervals. It is simply selected facts from the complete history of the cases kept up to date.

A cancer register is more than a file of index cards with names on them. A register starts with a case report and becomes a register only by the addition of subsequent information purposefully collected at regular intervals. To be most successful, the register should be an integral part of an operating program and should be located where the local program actually is carried on. This may be the state health department, the local health department, or both. Although a large amount of statistical information useful in a cancer control program can be obtained from a cancer register, a register is not primarily a means for collecting data for epidemiological studies.

A cancer register originating with a morbidity case report should be distinguished from diagnostic and pathological cancer registries. These latter are collections of case histories including pathologic material, sections of tissue, and relevant clinical history, findings, and results submitted by coöperating physicians. The sponsor of the registry receives the material for permanent file, reviews diagnoses, provides or obtains consultation on the pathology of difficult cases, prepares the material so that it can be used for study and research and, in some instances, conducts follow-up studies. The essential requirement for this registry is that each case be completely and accurately documented. It is not necessary that the cases reported provide a random sample of all existing cases, since the primary purpose is an accurate description of individual cases and not a basis for inferences concerning the entire population of persons with malignant neoplasms. A registry of this nature can be successfully maintained by the voluntary submission of material by clinicians and pathologists.

The primary uses of diagnostic and pathologic registries are to assemble data for research, especially in pathology, to furnish illustrative and demonstration material for medical schools, and to assist in the training of pathologists and clinicians. Frequently, expert diagnostic advice also is given by the agency operating the registry. These registries cannot provide reliable statistical information concerning morbidity from cancer of the kind described above. Due to the selection of the cases included, the data will not yield an unbiased estimate of the relative incidence of different types of neoplasms, nor can they form the basis for the computation of survival rates representative of the total population of cancer cases. A tumor registry can provide a very valuable specialized service. It does not furnish the type of statistical

data necessary for the evaluation of a cancer control program. The distinction between the function of this type of registry and that of a register growing out of a cancer morbidity reporting system should be kept clearly in mind so that each may be assigned its proper role in any program.

If it is to be most useful, a cancer register must be closely integrated with the entire cancer control program. Many elements of the program can be built around and guided by the statistical data from the morbidity reports. Moreover, the interest and coöperation of physicians and hospitals can be maintained by regularly making available to them not only summaries of their own experience but also composite summaries of the entire population included. The statistics should be collected, not as an end in themselves, but for the use which can be made of them.

If organized along the lines indicated above, a cancer morbidity reporting system and register can measure the magnitude of the problem by means of the number of new cases diagnosed and the number of cases treated per unit of population, the location of the problem by the geographic distribution of cases, the results of education and case finding activities by the stage of the disease at time of diagnosis, improvements in diagnosis by the proportion of diagnoses established by histological or other standard methods, advances in therapy by survival rates, adequacy of case holding by the proportion of cases which regularly return for reëxamination, and the success of control measures by trends in the incidence of different types of neoplasms. These are only some of the many services which can be rendered by the reporting of cancer cases.

Before starting cancer morbidity reporting and establishing a cancer register, a health department should formulate clearly its objectives and the uses which it plans to make of the data collected. The fact that some state or city has a particular plan in operation is no guarantee that that plan will meet the needs of another area.

From what has been said above, it should be apparent that a cancer reporting system patterned after that for communicable diseases whereby a single report is obtained on each case can fulfil only a limited number of the functions which have been discussed. Moreover, it fails to provide for one of the most essential services, subsequent follow-up of cases. On the other hand, a voluntary, partial-coverage cancer register, not operated as part of a complete morbidity reporting system, can provide follow-up information but cannot provide the other general statistical data which are equally important. Such registers fail to measure completely the magnitude of the problem, either at a particular moment or over a period of time. In addition, there always is the unanswered question of the representativeness of the data.

The specific details of a cancer reporting system must be adapted to the special needs of each state. At the same time, the greatest benefits will be derived if comparable data are obtained so that the experience of one state can be compared with that of other states. In recognition of this fact, the U. S. Public Health Service and the American Cancer Society have jointly developed standard cancer report forms. The Maryland State Health Department in coöperation with the Public Health Service has initiated a demonstration local cancer control program which includes the use of these forms in morbidity reporting and the establishment of a cancer register. Statistical procedures are being developed to measure each aspect of the program with special attention to the role of public health nurses. Copies of the manual outlining the details of the reporting system and

of the other statistical procedures can be obtained upon request. The National Cancer Institute is adding persons to its staff to consult with states which wish assistance in establishing cancer morbidity reporting and cancer registers.

I have mentioned only a few of the uses of statistics in a cancer control program. I have said nothing of the role of statistics in epidemiological investigations, in the evaluation of diagnostic tests and similar activities. However, I hope that I have conveyed my belief that statistical activities, if thoughtfully planned and competently executed, form an integral part of a cancer control program.

Recent Nutrition Surveys in Newfoundland

A conference on recent nutrition surveys in Newfoundland was conducted under the auspices of the Nutrition Foundation, New York City, April 4. An international group of physicians from Canada, Great Britain, and the United States reviewed the part which improved diet can play in reducing infant mortality, lowering the tuberculosis death rate, increasing the alertness of children, and decreasing the symptoms that nutritionists attribute to dietary deficiencies. The findings of a 1948 resurvey of nutrition in Newfoundland were released, supplementing the initial survey made in August, 1944. The full report is published in the April issue of the *Canadian Medical Association Journal.*

Among the physicians participating were Dr. W. R. Aykroyd, of the F.A.O., United Nations; Dr. Norman Jolliffe, Department of Health, New York City; Dr. O. H. Lowry, Professor of Pharmacology, Washington University, St. Louis, Mo.; Dr. Percy E. Moore, Department of National Health and Welfare, Canada; Dr. W. H. Sebrell, National Institutes of Health, Bethesda; Dr. R. E. Shank, Professor of Preventive Medicine, Washington University, St. Louis, Mo.; Dr. F. F. Tisdall, Pediatrician, University of Toronto; Dr. R. M. Wilder, Professor of Medicine, Mayo Foundation, Rochester, Minn.; Dr. P. C. Zamecnik, Harvard Medical School, Boston; and Dr. Charles G. King, Director, Nutrition Foundation, New York.

According to the Nutrition Foundation, the survey of 1944 revealed that malnutrition due to the lack of thiamine, riboflavin, niacin, vitamin A, and ascorbic acid was common. These deficiencies were found in association with extensive dental caries, poor muscular development and infant mortality and tuberculosis rates from two to three times as high as those encountered in populations of similar ancestry in more favored regions. Steps were taken to improve the situation, including the enrichment of flour with thiamine, riboflavin, niacin and iron and, after January, 1947, with calcium, as well as the fortification of margarine with vitamin A. Increased emphasis was placed on education in nutrition, together with limited distribution of dry milk and cod liver oil and concentrated orange juice. Of the 868 persons examined in 1944, 227 individuals were reëxamined four years later.

The infant mortality rate in the City of St. Johns dropped from the 1940–1944 average of 102 to the 1947 rate of 61. The death rate from pulmonary tuberculosis dropped from a five year average of 135 to 101 in 1946. The death rate from all causes ranged during the five year preceding period from 11.4 to 12.5, dropping to 10.4 in 1945 and 10.5 in 1946.

Chronic Disease

Diabetes Control in a Local Health Department *

HUGH L. C. WILKERSON, SENIOR SURGEON, AND MALCOLM J. FORD, SURGEON, F.A.P.H.A.

Diabetes Section, States Relations Division, Public Health Service, Federal Security Agency, Boston, Mass.

WHAT is diabetes control? Before the discovery of insulin, the average life expectancy of a child with diabetes was about 2 years. A diabetic adult lived for an average of about 8 years. It was difficult to manage diabetes in the individual clinically, and starvation diets provided the major control measures. Public health procedures could not be adapted to the diabetes problem.

Significant changes have occurred in comparatively recent years. With advances in insulin and diet therapy, the juvenile diabetic can now look forward to an ever-increasing life span. Today, the adult, who acquires diabetes which is diagnosed early, and who is given the best treatment provided by our present medical knowledge, may expect to have a longevity which approaches and in some instances surpasses that of the average American citizen of his age. Early detection improves the clinical prognosis and offers encouragement for the prevention of complications. Prompt and aggressive therapy by a competent physician usually presages a successful treatment regimen and a happy life. The proper psychological presentation of the treatment pattern encourages the individual and helps to give good mental adjustment to the required changes in habits. This, together with painstaking education of the diabetic individual in practical methods of self management, promotes both his mental and physical well-being.

Preventive measures in diabetes which may be put to practical use by the public are now available. These are provided by our knowledge of the common factor of hereditary susceptibility in diabetes, by the high incidence of obesity usually found as a forerunner of the disease, and by the frequency with which acute infection or exacerbation of chronic infection "lights up" the pathological process. Therefore, while we do not know the exact causative agent or the specific host factor responsible for diabetes, we do know enough about its course and conditional factors to define and delimit diabetes control. Early detection, prompt referral to a physician for competent treatment, and thorough education of the diabetic patient and his family constitute important components of diabetes control in the individual and in the community. To these control factors must be added the problems of employment adjustment and the provision of adequate clinical and hospital facilities for the diabetic population.

Interpret the death rates from dia-

* Presented at a Joint Session of the Epidemiology, Health Officers, and Statistics Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

betes as you wish, but as public health workers we should concern ourselves more with the current problems of the living diabetics. Living diabetics are increasing in number. Various experts have estimated that there are one million known diabetics in the United States, and recent large-scale laboratory studies of population groups in several communities have been used as bases for estimates that the number of unknown cases represents a comparable figure. People with diabetes are living longer, and with longer life have come premature arteriosclerotic complications particularly in those cases poorly controlled, where invalidism often results. In many and probably most of such complicated cases the disease was not recognized and treated until gross symptoms were evident. The disease thus takes a definite place in the health picture of any community and should, therefore, be of interest to the local health authority.

Diabetes has several definite characteristics which set it apart from the other members of the chronic disease group. Its treatment is carried out almost entirely by the individual patient under the supervision of his physician. There is no permanent remedy, but with good treatment the patient survives for a normal span of life. People with properly treated diabetes have been outstanding in sports, and in professional and political life; however, if diabetes is improperly controlled, it will cause hospital beds to be filled and will use up badly needed nursing services. The efficiency and productivity of the average diabetic patient is excellent when his disease is under control. However, he can easily become a drain on society when he is improperly treated and when his disease is poorly managed.

The present state of medical knowledge is such as to permit an active community program in diabetes control. There are relatively inexpensive and simple laboratory procedures available to aid in the detection and diagnosis of diabetes. As far as is known, there occurs in all cases of diabetes mellitus an increase in the amount of blood sugar, and in nearly all cases an excretion of sugar in the urine. Since 1922, there has been a corrective treatment available, in the form of insulin, which can restore patients from diabetic coma and impending death to a condition approximating complete health.

How can public health workers contribute to the health of a community through a diabetes control program? First, there is every indication that there are many undetected cases of diabetes in most population groups. In the survey conducted by the Public Health Service in Oxford, Mass., in 1946, almost as many unknown cases of diabetes were found as there were known cases. Every internist has experienced the situation where persons were first informed that they had diabetes when they were aroused from a diabetic coma. In one large medical institution, the disease of one of every six diabetics who are seen is discovered in a general examination, which is usually given for some other condition. A large percentage of the cases of diabetes found as a result of life insurance examinations show no history of the usual symptoms of diabetes.

Second, the personal aspect of the treatment of diabetes necessitates careful patient education in the basic principles of diabetes therapy. These two points suggest some of the opportunities which public health workers have to assist the practising medical profession in diabetes control. Since professional public health workers are schooled in diagnostic screening procedures and in health education, the application of these two skills, in close coöperation with organized medicine, will improve the diabetes control situation in almost any community. The Diabetes Section of the Public Health Service has been

in existence for two years. During this time diabetes prevalence studies have been made. Diabetes Demonstration Units have been established and have functioned as part of the local health departments in Jacksonville, Fla., and in Brookline, Mass. These units have been engaged in developing and demonstrating various ways of applying public health methods in diabetes control.

The unit in Jacksonville was established upon the invitation of the Duval County Medical Society. Personnel specially trained in diabetes mellitus were furnished as an intact unit by the Public Health Service. Valuable contributions to the program were made by the state and local health departments and necessary groups. The local medical society through its Diabetes Advisory Committee, has given support and guidance to the program. The Public Health Service personnel assigned to the Jacksonville demonstration unit includes 1 public health physician, 1 public health nurse, 1 nutritionist, 2 laboratory technicians and a secretary. A Medical Advisory Committee, composed of local physicians and public health workers, has reviewed all phases of the program with the director of the unit, has given advice on new projects, and has acted as liaison with the medical profession. This advisory committee includes two prominent internists, one of whom is director of the Diabetes Clinic at the County Hospital; the state, county, and city health officers; and a representative from the local Negro medical society.

At the start of the program in Jacksonville a register of known diabetics was set up. Diabetes reporting was not required, but it was invited, with an offer of valuable service in return. Names of diabetic patients were furnished by medical practitioners in the county hospital clinic and by other sources, including the Visiting Nurses' Association and patients themselves. Physicians have continued to send in the names of new patients, and periodic requests are made of all physicians to furnish names of new patients so that the register may be kept up-to-date. This register has proved useful, and is expected to furnish valuable information. At present, it contains a total of 845 names.

The diabetes control program in Brookline is conducted by the local health department with assistance from the Diabetes Section of the Public Health Service. Real efforts have been exerted to make this a true community project. The sponsorship of the program, most of the policy decisions, and a significant amount of the community work are provided by a lay advisory committee and a Medical Advisory Committee. The lay committee—The Diabetes Control Committee of Brookline—is composed of 26 local residents, interested and active in civic and community affairs. The Medical Advisory Committee has a membership of 13 Brookline physicians, who serve because of their special interest in diabetes and in community activities.

The Brookline experience indicates that one effective method of stimulating interest in diabetes is to make it convenient for people to take advantage of testing services. Temporary testing facilities are set up in various sections of the town. These temporary screening clinics usually operate in each section for a week or more, and move about the town. In addition to the neighborhood or sectional temporary screening stations, regular diabetes testing and diagnostic clinics are held in the health department building both afternoons and evenings. Persons of all ages are admitted to any of these clinics, preferably 1 to 2 hours after a full meal. At the first visit a urine sugar test and a capillary blood sugar test are given. If the values found as a result of these tests are within normal limits. the patient is informed that there is no labora-

tory evidence of abnormal findings at that time, and his physician is notified of the actual values. If the values are higher than normal the patient is contacted by letter or telephone and given another definite appointment for a recheck. His diet should be relatively high in carbohydrates at each meal for at least 3 days prior to the reëxamination. He is instructed to eat a meal containing approximately 100 gm. of carbohydrates 1 hour before his appointment, and is given specific instructions about this meal. At the second visit, another urine sugar test is made, and both capillary and venous blood are analyzed. If further study is indicated, the patient is then given an appointment for a glucose tolerance test. In the demonstration units no definite diagnosis of diabetes is given to the patient. He may be told that he has higher sugar values than normal, but he is not informed that he has diabetes. The patient is always referred to his own physician for diagnosis and this physician is always notified of the results of all the laboratory work.

In Brookline, to date, 3,720 people have been tested and 71 cases of previously unknown diabetes detected. This is not, of course, a random sample. But there has been no effort to select the group tested.

In November, 1947, when a mass chest x-ray survey was being conducted by the Brookline Health Department, diabetes testing facilities were set up, and handbills announcing the diabetes detection program were circulated among the group being x-rayed. Ten new cases of tuberculosis (or 0.16 per cent) were found among about 6,000 persons x-rayed. About 2,100 of these same people, or about one-third of those x-rayed, responded to the offer of diabetes tests at the same visit. Limited laboratory facilities prevented testing of additional people. Eighteen previously unknown diabetics (or 0.9 per cent) were detected in this smaller group. The diabetes discovery rate was more than five times as high as the tuberculosis discovery rate.

The methods used for screening population groups for diabetes have differed in some minor respects but essentially consist of post-prandial analyses of both blood and urine for sugar. The tests are preferably given to the subjects from 1 to 2 hours after they have eaten a full meal. Either capillary or venous blood sugar determinations are satisfactory. In Brookline, mostly capillary blood specimens have been collected, and in Jacksonville venous specimens have usually been obtained. If the tests show hyperglycemia or glycosuria, additional or recheck tests are made. These may consist either of a repetition of the same type of examination or performance of the standard glucose tolerance test. Those persons with confirmed abnormal laboratory findings are urged to see their family doctor. The laboratory results are sent to this doctor. The responsibility for interpretation of the laboratory results and for a diagnosis of diabetes rests with the patient's physician.

Different approaches to testing the population were developed in the two demonstration areas. In Jacksonville various population groups were contacted. One of the most successful projects was the testing of the blood relatives of diabetics. When a case of known diabetes is brought to the attention of the demonstration unit, with clearance from the attending physician, one of the public health nurses assigned to the unit itself or to one of the several coöperating agencies calls on the patient. A list of relatives living within the area is obtained. Relatives are then sent a form letter describing the high incidence of diabetes among relatives of known diabetics, and explaining how frequently the disease can occur without

detection. They are offered an opportunity to be tested, and an appointment is made for diabetes testing at the health department. The source diabetic is also informed of the time and place of his relative's appointment, and is urged to assist the health officer in the effort to get the relative tested. In a group of 753 relatives tested approximately 3.7 per cent of previously undetected diabetes has been found.

Education of the diabetic patient is a *sine qua non* of proper management. There is an opportunity for the local health department to coöperate with and assist the physician in the accomplishment of this objective. Recognizing that there is no objective of diabetes control more important than education of the patient, the Jacksonville unit organized with the coöperation of the medical advisory groups a public health class for diabetics. The demonstration unit furnished the instructors, the State Board of Health provided the materials, and the Duval County Hospital the classroom. The Medical Advisory Committee reviewed the plans and content of the educational program. The class was publicized through letters to local physicians and through notices in each of the four local newspapers. As a result, 125 persons attended the first session of the class. A total of 415 persons have already attended the series of six classes, each of which lasts 2 hours. About half of these people have been referred by private physicians.

The instruction is given by the unit physician, the public health nurse, and the nutritionist. The following topics are included in the total of 12 hours of classroom instruction.

Topics for Classroom Instruction

The nature of diabetes
Insulin—its source and action
Insulin reaction—its avoidance
Nutrition and diabetes
  Diet—Carbohydrates, Proteins, Fats
Complications—their prevention
  Infection, Sickness, Personal Hygiene
Sugar in blood and urine
  Urine testing methods
  Blood sugar analysis
Travel problem in diabetes
Selection and preparation of menus and lunches
Discussion period

The classes are conducted mainly by the discussion method, and participation by the patients is encouraged. Generous use is made of visual aids, such as moving pictures, charts and models (including food models). One class was given in a rural health center in the surrounding county area in order to bring this educational service directly to the consumer group.

An attempt was made in these classes to learn what the average diabetic patient knows about diabetes. A simple pre-test, based on the principles necessary for the adequate and accurate control of diabetes was given to diabetics attending their first lecture. The test was made as simple as possible, with only a "yes" or "no" answer required.

It is often quite difficult for the patient to acquire all the knowledge which he must have of the various techniques concerned with the treatment of diabetes. The patient must become adjusted and acquire wholesome psychological and philosophical attitudes toward his diabetic condition. In addition, he must learn several technical procedures which may be difficult if he does not possess the necessary background or orientation. The intricacies of diet substitution, of sterile techniques, and the injection of insulin seem to be particularly difficult for some age groups, particularly for children and for women past middle age. It is in the latter group, especially, that diabetes seems to be concentrated. Thus, follow-up is frequently found necessary after the initial course of instruction. The patient needs encouragement as well as a general review of his under-

standing and adherence to the diabetic regime.

In the Jacksonville unit, public health nurses and dietitians, under the direction of the physician in charge, take care of this follow-up when necessary, through home visits. The visits are made either at the request of the patient or his physician. In consultation with the Medical Advisory Committee a regular schedule of home visits is now being worked out. It is planned that every patient will be visited in his home, if possible, and will be encouraged to keep regular appointments for check-ups with his family doctor. This schedule will provide an opportunity for seeing the patient in his home environment and to study all the factors which affect his adherence to the treatment prescribed by his physician. The nurses, of course, can be of invaluable service in this phase of the control program. Almost without exception, the patients are deeply appreciative of this service and in the cases of invalids with diabetes, it is particularly valuable and always appreciated.

It is fortunate that a tolerance test is necessary on only a relatively few. It usually takes about 3 hours to complete the standard glucose tolerance test. During this time, however, the patient is actually busy with the doctor, nurse, or technician for little over ½ hour. The patient usually has nothing to do during the remainder of this period, except to wait for the next part of the test. Consequently, this interval has been used to good advantage by the health staff for giving instruction in causation factors in diabetes. This instruction includes a general discussion of the basic physiology involved in the glucose tolerance test and of the general aspects of diabetes. Since many of the persons waiting to be examined are overweight, an explanation of obesity and how it may be controlled is usually given. The discussions are then supplemented by films and pamphlets. We have found that the patients are particularly receptive when the tests are being performed, and we believe that, while the number reached in this manner may be small, a great deal of permanent value is accomplished.

A monthly news letter which goes to all known diabetic patients listed on the Jacksonville registry provides still another avenue for diabetes education. These one page bulletins, which are written in as simple language as possible for diabetic patients, are prepared and distributed in coöperation with the Medical Advisory Group and the local health agencies. They stress some of the important aspects of diabetes control and attempt to keep the patient informed of new advances in diabetic knowledge, new equipment, and timely advice on such matters as diet, avoidance of colds, foot infections, etc. The person with diabetes has a disease that will be with him the rest of his life and he needs constant encouragement, as well as the reiteration of the principles of adequate diabetes control, if he is to pay careful attention to a proper diabetic regime continuously for a period of many years. The repetition of some or all of the instruction classes, but particularly the regular distribution of this short and stimulating news letter goes far toward accomplishing this objective.

We have had the important coöperation of local pharmacists, in Jacksonville particularly, in offering aid and publicity for the various diabetes projects. The diabetic patient sees his pharmacist much more often than he sees his physician. He must purchase his insulin at approximately 2 to 4 week intervals. He needs other diabetic supplies, such as needles, syringes, cotton, etc. The local pharmaceutical association in Jacksonville coöperated in a recent campaign to acquaint diabetics in the area with the diabetes control program.

One of the projects of the American Diabetes Association is the sponsoring of local diabetes associations, which are divided into lay and professional sections. Diabetics are encouraged to join the lay sections. The professional sections, on the other hand, have excellent opportunities to put emphasis on improvement in detection and treatment techniques. The personnel of demonstration units can and have been active in initiating and coöperating in the organization of local diabetes associations. Much interest is nearly always shown by both diabetics and professional people and it can be predicted that once such a local program is under way it will be highly successful.

The nutritionist or dietitian associated with the health department can give valuable assistance in a diabetes control program. In coöperation with local dietetic groups there can be brought about the standardization of diabetic diets for the local area.

As is true with any public health program, relations with the practising medical profession must be cordial and cooperative if the diabetes control program is to be ultimately successful. Every attempt has been made to foster such a spirit of unity and concord in local areas. Medical advisory committees have been organized and physicians are constantly advised and informed, through their medical societies, of the progress and major aspects of the program. As might be expected, at the start of a new program, the physicians and other health workers, official and voluntary, at first viewed the diabetes control program with a judicious but not uncritical eye. As the details of the program unfolded before the physicians in the demonstration areas, however, they have expressed their appreciation and coöperation.

Undoubtedly there remains more to be done in constructing plans of control of diabetes on a mass basis and in setting up comprehensive diabetes programs which will be suitable for all local health departments. However, it seems that several facts are established through the experience of the demonstration units—that diabetes is amenable to public health control measures, and that a basic pattern for a workable control program has begun to emerge. Progress in the detection and management of diabetes is a coöperative responsibility. With the active help and support of the practising physician of official and voluntary health organizations, of nurses, dietitians, and all other health workers, we can make important progress toward attaining the goal of better diabetes control in our community and in our nation.

SUMMARY

Diabetes control is a community as well as an individual health problem. Diabetes, one of the chronic diseases which have long been neglected, should have a place in a local health department program, and diabetes control should be integrated with other chronic disease control programs where such programs exist.

Active public health programs in diabetes in Jacksonville, Fla., and Brookline, Mass., are described as coöperative endeavors between the Diabetes Section of the Public Health Service and local health departments. The objectives of the diabetes control program are primarily case finding (early detection), referral to practising physicians for treatment, and education of the public in general, and of the diabetic patient in particular. The procedures used in screening for diabetes and in the various phases of the diabetes educational program are described. Of particular significance are the diabetes discovery rates in the demonstration control programs, especially among the relatives of known cases of diabetes mellitus.

A Health Officer Survey of a Medical Care Program*

WILLIAM H. F. WARTHEN, M.D., M.P.H., F.A.P.H.A.

Deputy State and County Health Officer, Towson, Md.

THE health officers of the 23 counties of Maryland were challenged more than three years ago to put into effect an extensive and quite novel addition to the plans and activities of their several health departments, a program of medical care for the indigent and medically indigent. They had followed with keen interest the origins of the movement and the studies and exhaustive discussions of those who were designated to find a practical solution to the difficult problem. The underlying philosophy of the plan finally adopted was by no means unfamiliar to the health officers, for in 1944 the Committee on Medical Care of the State Planning Commission had made a report of its three year study to the Medical and Chirurgical Faculty of Maryland.[1] On the contrary, interest rode high and the physicians in charge of the local health departments of the state were thus enthusiastically ready to go when the legislature in 1945 provided for the actual inauguration and conduct of a medical care program by the state and local health departments.[2] It is, therefore, not surprising that the health officers of Maryland counties have enjoyed planning and putting into effect their own local medical care programs and that their efforts have resulted in the attainment of a very considerable degree of success. Our health officers agree that improvement both in medical care and in the usual preventive services has resulted from the joint efforts of the staffs of the local health departments and of the central Bureau of Medical Services of the State Health Department whose specific function it is to carry out the provisions of the medical care law.

In the counties of Maryland the medical care program is designed to reach persons receiving public assistance and those not on relief but who are unable to pay for needed medical care. Those individuals on public assistance, referred to as the "indigent," total about 17,000. They are certified periodically to the county health department by the county welfare department and are automatically supplied with identification cards establishing their eligibility for a 6 month period. Persons not on relief but not able to pay for needed medical care may make application for services to the county health department. If their income is within the limitations established by the program they are certified for eligibility for curative services for a specific period of time. In this certification the health officer has broad discretionary authority with regard to evaluating social, medical, and economic factors of the individual or family. Although the scope of medical care services varies from county to county, home and office care by physicians, prescribed drugs and acute dental care are provided in all counties. There is provision in the majority of the

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 12, 1948.

counties for hospital calls, acute and elective surgery, maternity care, consultations, and diagnostic laboratory services. Of the 23 counties, 15 provide elective dental care including dentures. In all counties full use is made of the existing clinical programs of the health department such as the prenatal, child hygiene, venereal disease, and tuberculosis clinics.

The physicians, judging from their actions and expressed opinions at state and county medical societies have supported the medical care program from the beginning. Their active interest has continued. Physicians are represented on the Committee on Medical Care of the State Planning Commission, and on the State Council on Medical Care which guides the Board of Health, and on each of the county advisory committees. The majority of physicians are taking an active part in the program, and the same is true of the dentists and pharmacists. Payment is on the fee-for-service principle following a uniform fee schedule recommended by the Council on Medical Care. The individual private physician submits at the end of each month a simplified medical report for each patient under the program, whom he has treated during the month. This report is first reviewed and approved by the county health officer and then sent to the state office from which payment is issued. Of the approximately 25,000 persons in the counties who are in possession of certificates of eligibility, about 5,000 receive physicians' services each month. From the beginning of the program 957 physicians have participated. A substantial number of these physicians have their offices in Baltimore City, not in any county, and a few are out of the state. There are 693 physicians in the counties, and of these 592, or 87 per cent, have participated in the medical care program. Each month between 450 and 500 physicians participate in the program.

Although no attempt has been made formally to determine, in their own words, what the recipients think of the program and its services, the county health officers receive daily the opinions of many patients receiving care. Almost universally there is satisfaction on the part of recipients and gratitude for the office and home medical services given them by the nearby physicians and dentists of their own choice. The health officer is pleased to note the general response to the medical care program, both by those who give and by those who receive curative services. Before the program began health officers were embarrassed by having many persons apply to them for medical care, and in most cases they were unable to render any assistance. When such persons were, of necessity, referred to a private physician, the health officer felt that the service rendered by the physician to the patient was regarded as a personal favor to the health officer.

Fuller accounts of the basic concepts, the beginnings and the progress of a state-health-department-sponsored medical care program as illustrated by the experiences in Maryland have already appeared.[3-5] A further description of the many novel administrative techniques which had to be developed in this program, many of them unique patterns for the future, a few almost completely without precedent, would not be appropriate at this present discussion. Rather, I prefer to speak about how the health officers of Maryland have attempted to solve some of the problems which arose when they were called on to develop a workable administrative machinery for integrating the varied services required for medical care, into the already existing system of preventive services. I shall point out a few representative situations and how we, as local health officers, have reacted to them.

As a background of the actions and

reactions of the health officers of Maryland to the medical care program, it is necessary to point out that in Maryland the delegation of administrative responsibility for the operation of the plan was made possible by the complete system of county health departments which has been in operation in the state during the last two decades. Each of the 23 counties has a health department, with at least a minimum staff, consisting of a physician who is the health officer, two or more public health nurses, and clerical personnel, all serving on a full-time basis. In the larger counties this minimum staff is supplemented by assistant health officers, dentists, additional nurses and nursing supervisors, medical-social workers, sanitarians, and other auxiliary personnel. The administrative head of each county department serves both as county health officer and deputy state health officer. He is appointed by the county board of health, but his appointment must be approved by the State Board of Health. As county health officer, he is responsible to the county board of health, and as deputy state health officer, he is responsible to the State Director of Health. The administration of the local medical care program is entrusted to the health officer in his capacity as deputy state health officer. The health officer thus has the responsibility for developing an efficient curative program and, at the same time, an opportunity to strengthen and enlarge the already existing preventive services.

It was early apparent to each health officer, just before the medical care program was inaugurated in his department, that this new function needed to be publicized and interpreted promptly to as many people as possible in the community. This was done, first, by the usual methods of disseminating information: addresses to the medical association, letters to physicians, dentists, and pharmacists, news releases, conferences with heads of official and nonofficial agencies, and informal talks by the health officer with professional and lay people of his acquaintance in the community. This sudden increase in his contacts helped him immeasurably to publicize his existing preventive program, because he would not and did not want to explain and teach the services of one program without doing so for the other. The continuing interpretation of his entire program to the profession, to community agencies, and through them to the public, was facilitated by the development of a new and valuable administrative aid, the county advisory committee on medical care. This committee includes representatives of the medical, dental, and pharmaceutical professions, of the local board of health, welfare agencies, board of education, nursing and lay health organizations. If health officers were asked to name the single most useful and effective factor in the operation of the medical care program and its integration with the preventive program, the almost unanimous choice would be the county advisory committee, functioning with their imaginative leadership and intimately associated in its deliberations with the statewide advisory body of which the State Director of the Bureau of Medical Services acts as secretary.

The multiplication in the number of contacts between the health officer and the medical and dental professions resulting from the inauguration of the medical care program has been welcomed by the health officer who knows that more contacts mean increasing his services both preventive and curative to the professions and to the people. He has found that he should have a personal interview with every new physician who establishes a practice in the county, and in some counties he can periodically visit all the private physicians. He has learned that when a friendly coöperative relationship has been established with a

physician, a regular visit by one of his public health nurses, offering her help in his work with his own patients, is a valuable aid in enhancing good will for the health department.

Many health departments had already established master index files of all preventive services rendered to an individual, but with the establishment of the medical care program there has arisen the evident need of an index card file of all services, both curative and preventive, in each county. Some departments have started this all-service file for securing and exchanging information of services rendered or to be rendered, particularly by public health nurses. They will find the use of the file to be of value in improving the efficiency of their visits to individuals and families. In addition, the department file of summary sheets of medical care services specifically rendered an individual should be active, and the records carefully reviewed periodically by the health officer to secure information to be used, not only when he confers with physicians about particular cases, but also for transmittal to the public health nurses who may more intelligently deal with their patients.

The need has become more evident, since the beginning of the medical care program, for making preventive as well as curative services readily available to a segment of the population which has for the most part not previously been reached by the health department. Prenatal and infant and preschool hygiene clinics are being enlarged and expanded as well as school health services. Consultation clinics, often developed in the past around preventive programs in such fields as obstetrics, pediatrics, and orthopedics should now be expanded in new fields such as internal medicine, psychiatry, gynecology, and surgery. In some counties it will be feasible to combine several specialized clinics into a general diagnostic clinic. Patients of the medical care program can and should be encouraged to receive two of the most valuable aids to diagnosis already in the preventive program, an x-ray of the chest and chemical and microscopic examination of the urine at clinics already being conducted.

A bedside nursing service is certainly recognized as perhaps the means of choice in bringing both the curative and preventive services directly to the individual and family by the public health nurse who, in bedside work, goes over the doorstep and into the very sickroom of the patient. Of course, the paucity of public health nurses in anything approaching a practical ratio of nurse to population is the present barrier in making this type of nursing service an immediate part of the health department's program, particularly in the larger counties. However, three counties under the able sponsorship of the State Division of Public Health Nursing have inaugurated trial programs of bedside nursing and patterns for the future, and in other counties are being successfully developed.

There are, of course, other improvements to be made along the lines of coordinating the preventive and curative services of health departments. One of these is the extension and enlargement of dental services in the three large areas of endeavor: (1) preventive, (2) preventive-curative, and (3) restorative. Vigorous efforts should be made by health officers to effect as soon as possible a closer day-by-day working relationship between the department's curative services and the individual practitioner of dentistry. It is expected shortly to arrive at specific recommendations as to ways of improving distribution of dental health information to private dentists when a contemplated special committee of health officers for public health education standards is activated.

Experience in the medical care pro-

gram has shown the health officer that laboratory service needs to be enlarged, as is necessary in order to meet the growing demands placed upon it by patients actually treated clinically in the medical care program. Already the staffs of the 11 branch laboratories of the State Department of Health have been enlarged in order that they may perform clinical laboratory tests for medical care patients. Most of these laboratories are now able to offer to the physician the usual hematologic examinations, blood chemistry, urinalysis, serologic tests, and bacteriologic examinations. In addition to these expansions, steps should be taken to inform continuingly all the private physicians of the county concerning the exact nature of laboratory services which are currently available. Health officers believe that leaflets should be prepared and issued by the State Bureau of Bacteriology to private physicians and county health departments relating the clinical features of the more common diseases with the types of tests which can be made and the character, value, interpretations, and limitations of the various tests.

In May, 1947, a little more than two years after medical care became a reality in Maryland the Director of Health appointed a committee of four health officers and two representatives of the central office to study and make recommendations concerning the ways and means for establishing policies to promote closer coördination between the preventive and curative services. Before making its report [6] the committee shared its findings with the health officers of all the counties. The interchange of experiences at this meeting was acclaimed by the health officers as a factor of first importance in indicating the practical steps to be taken in each county toward unifying the preventive and curative services.

The health officers of Maryland believe that their efforts to establish and operate the local medical care program and to coördinate the preventive and curative services have been attended by measurable and demonstrable success. The individual health officer has shown an eagerness to carry on the medical care program because he sees in it an opportunity for enlarging what he considers to be his own and his staff's usefulness in the public health field. He has looked upon the inauguration and operation of his medical care program as a forthright challenge of his talents and abilities to devise and carry out an intricate series of administrative procedures. More than any other health department function in recent years, the medical care program has given an opportunity, long sought by many health officers, for expanding his public health and civic leadership. He has been fortunate in having the guidance and service of an alert State Bureau of Medical Services, closely and actively associated with him in the work of formulating and carrying out county as well as statewide medical care policies. It is this working together of the health officer and his Bureau of Medical Services and his own advisory groups that has made medical care an exciting and satisfying administrative experience to the health officers in the counties of Maryland.

Nutrition Course for Students of Public Health*

JOHN J. HANLON, M.D., M.P.H., F.A.P.H.A., AND ADELIA M. BEEUWKES, M.S., F.A.P.H.A.

University of Michigan School of Public Health, Ann Arbor, Mich.

NUTRITION represents one of the relatively newer activities in public health work. This is due in part to problems arising out of the recent war and in part to a natural maturation of the field of public health. These two processes have brought about an increased awareness and demand on the part of the public, accompanied by an increased interest on the part of some of the various members of the public health profession in problems and programs relating to public health nutrition.

The fulfillment of these demands and interests has been hampered by four outstanding factors: (a) the inadequate numbers of all types of public health personnel, among whom are now included nutritionists; (b) some uncertainty concerning the modus operandi of a satisfactory program of public health nutrition; (c) misunderstanding concerning those persons in the public health family who should be charged with responsibility for work in the field of public health nutrition; and (d) the relative lack of a satisfactory, time-proven pattern for the teaching of public health nutrition. The primary purpose of this paper is to discuss the last of these four factors. It is obviously impossible to do so, however, without first giving some consideration to the other three.

The report *Local Health Units for the Nation* has brought into the national consciousness the discrepancies between existing and needed personnel in all branches of public health service. While public health nutritionists are not specifically considered in that report, its conclusions apply to that professional group, perhaps all the more so, because of the relative newness of applied promotive nutritional work in the public health program. Considerable variation exists in terms of the numbers of workers employed by health agencies specifically for work in nutrition. Data presented at the nutrition section of the National Health Assembly in May, 1948, indicated a total of 203 positions in public health nutrition in the 51 state and territorial health agencies. Of these, 35 were unfilled. At the present time (August, 1948) 7 of the state health agencies have no nutritionists in their employ, in 3 instances because no position exists and in 4 instances because of vacancies. The number of positions for nutritionists in state health agencies ranges from none in the 3 instances referred to above (Nevada, South Dakota, and Wyoming) to a maximum of ten in each of 2 states, the mode being about 2 positions.

One cannot help receiving the unfortunate impression that at the present time considerable misunderstanding and confusion exists with regard to the desired content and purposes of a program

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

in public health nutrition. Many public health workers look upon nutrition as a highly specialized field, success in which depends entirely upon the efforts of a few specially trained and interested physicians and nutritionists. One reason for this is that, all too often, nutrition programs are considered to be synonymous with diet therapy or with group feeding. Another possible reason is the considerable interest in, and possible over-emphasis on, the many nutrition surveys that have been conducted during the past 10 or 15 years. Studies such as these, while valuable in terms of determining base lines and research technics, are sometimes misinterpreted as representing the epitome of a complete satisfactory public health nutrition program. It should be remembered that but little control of tuberculosis would be accomplished if tuberculosis programs consisted merely of the development of diagnostic methods and the determination of the general level of infection in selected groups of the population. These activities simply constitute a starting point for the achievement of the ultimate goal of control.

Many other factors lead to a lack of interest on the part of many public health workers. There is a widespread tendency to consider nutrition only in a negative sense rather than from a preventive and promotive viewpoint. A failure to appreciate the extent and seriousness of the total problem has led some to regard any nutrition program as somewhat of a frill, to be engaged in when funds, particularly outside funds, are plentiful, and quickly dropped when they become scarce. Still others consider nutritional problems to be so intangible as to make it impossible to weave a practical, fruitful approach into the fabric of the total public health program.

It is appropriate, therefore, to inquire into the manner in which health agencies might concern themselves with nutrition. The public health approach must of necessity differ from other approaches to the subject. The agronomist is primarily concerned with the production of foodstuffs, the home economist with the proper preparation of foods, the biochemist with the minutiae of food assessment and the analysis of materials from the body which may reflect adequacy or inadequacy of intake and use of the component parts of the diet, and the clinician with the physical signs and symptoms of nutritional adequacy or deficiency. The public health worker, on the other hand, cannot restrict his interest and concern to any one or several of these. His approach to nutrition, as in the case of any other problem with which he is confronted, must be of a practical down-to-earth nature, viewing the people as an ultimate whole rather than as isolated individuals. The primary job at hand is to assist people in general in applying what scientific information is available at present in order that they may achieve a longer, healthier, more fruitful existence. To reach this goal requires a synthesis of many viewpoints: economic, sociological, clinical and educational, to mention but a few.

Fundamentally the program must take the form of continuous public education, assisting people in their efforts to meet their nutritional problems successfully. To accomplish this involves the breakdown, with the consent and coöperation of the public, of faulty traditional dietary habits, and the translation of scientific dietary analysis and planning into readily understood terms used commonly by the public. To alter ingrained habits and customs, especially those related to a function as personal as eating, is usually accomplished slowly and with great difficulty. To do so involves dealing with racial, regional, and familial customs; with prides, prejudices, superstitions and fears. The only successful approach is one which maneuvers com-

munity thought into the position of itself recognizing the needs and the remedies at hand.

To make a special, pointed attempt to accomplish these ends, all too often gives the impression that the health department is trying to sell the public a "bill of goods." One of the best ways of avoiding this unfortunate interpretation is to integrate applied nutrition into as many phases of the general public health program as is possible and the number of possibilities for doing this is surprisingly high. There are very few if any cases on the public health nurse's roster, for example, that do not need and cannot be given some simple but pertinent instruction in nutrition. Surely this is important in cases of acute communicable diseases, tuberculosis, and many non-communicable diseases such as diabetes and heart disease with which public health nurses are becoming increasingly concerned. Prenatal and well baby conferences offer particularly fruitful avenues of approach. The school health program provides an opportunity to show not only how the school lunch program may best be carried out, but also how sound nutrition information can be presented dramatically and effectively in the study of geography, economics, civics, and even arithmetic. Beyond this, with the general public in mind, the overall community health education program should give a fair share of attention to discussions, news releases, and radio talks on subjects relating to nutrition.

The medical personnel of the health department, in addition to having available all of the avenues of approach mentioned above, may work through another channel, the local members of the medical profession. In consultations, informal contacts, and talks given at medical society meetings, much might be done to increase the extent to which the private practitioners are nutrition conscious. The offering of nutrition consultation services to private physicians might be worth while in attempting to accomplish this end.

Most apt to be forgotten is the public health engineer or sanitarian, who, of all public health personnel, actually is most intimately concerned with food. It is he who visits the dairies, milk plants, restaurants, and food stores. If assisted to a wider horizon he may do much more than supervise the bacterial quality of food materials. His contacts with dairy farmers very often lead to discussions of various types of cattle feed and their effect on general health and function. To transfer conclusions to the human population is but a short step, although the taking of that step has already required the passage of several centuries.

With these few brief examples in mind we may answer perhaps more adequately the question—for whom should courses in public health nutrition be designed? If there is a shortage of nutrition specialists and of funds with which to employ them generally, and if all of the diverse professional types working in public health have a very real potential contribution to make in this area, then why not design the course in public health nutrition to meet the needs of the broader professional group.

It is obvious that the course should not be limited to a study of the biochemical constitution of foods, average daily requirements of essential food factors, and the consequences of an inadequate supply or use of them. Too often courses in nutrition for public health workers have stopped here. This is wholly inadequate. It is easily possible to possess a considerable mass of scientific facts and yet, for various reasons, be unable to apply them for the betterment of the people.

To begin with, it would seem worth while to devote some time to a consideration of the relationship between the nutritional condition of people and

their historical, economic, political, and cultural progress; in other words, food and the welfare of nations. Intimately interwoven with this, of necessity, is a consideration of the history of the science of nutrition and its application. The student should have a proper background and incentive for going on to study the biochemical, physiological and clinical aspects of the subject. In this regard it is strongly felt that a sound understanding of the physiologic reasons for essential nutrient factors, their natural sources, the methods of their use by the body, and the consequences of their inadequacy is of far more importance than committing to memory daily dietary requirements, the structural formulae of vitamins, and other similar numerical data which experience has shown to be changed from time to time and to have but limited practical application.

Bear in mind that we are confronted with the problem of providing students with a practical approach to assisting the family in the hills of Kentucky, on the plains of Nebraska, and the streets of New York in making the most of what they have readily available. It is well that the student learn to face squarely the environmental limitations of each person, each family, each community, and each nation with which they might deal. One of the most common recent American errors has been the attempt to force people and circumstances to fit artificial or scientific standards. The danger of falling into that attractive trap is particularly great in the field of nutrition where there exist so few obvious manifestations on which to base action.

A study of the many underlying reasons for dietary inadequacy, is, therefore, essential. Attention should be given to dietary customs, superstitions, fads and fallacies, and a study made of factors such as economics, climate, soil, and geography which may influence the food supply and nutrition of people. Special consideration should be given to phases of life which present unusual or unique nutritional demands or problems. Here, the periods of pregnancy, infancy, illness, and old age are worthy of particular note.

Finally, and serving as the focal point of all the foregoing, there should be provided ample time for discussion of the place that nutrition activities do and might occupy in the total general public health program. The organization and content of existing programs should be reviewed and suggestions for more effective programs elicited. The functions and use of state or regional nutrition specialists should be presented, placing particular stress upon their positions as educational expeditors, field consultants and inservice-trainers for the rest of the public health staff in the area. Specific attention should be given to school and industrial lunch programs as educational as well as feeding enterprises, which reach back into the home. Perhaps of greatest educational impact would be informal discussions of the potential contributions of each member of the class and of each professional group to the public health nutrition program. In attempting to do so, the case history approach may be used to considerable advantage.

The appeal of a course such as this is best indicated first by the types of students who elect to take it, and second by their response to the material presented, measured roughly in terms of sustained interest and participation. It has been interesting to observe the increasing attention which all types of public health students have been giving to the subject of nutrition. During the 3 academic years, 1945–1948, at the University of Michigan School of Public Health for example, the courses in public health nutrition have been elected by a total of 214 individuals, only 9 of whom were specialists in the field. The

heterogeneity of the remainder is worthy of mention. The course was taken by 153, or about 100 per cent of the public health nurses, 23 or about 50 per cent of the health educators, 19 or about 40 per cent of the health officers, 7 or about 20 per cent of the specialists in environmental health, 2 public health laboratory workers, and 1 statistician. In addition, and from other schools of the university, there were 102 or 100 per cent of the dental hygienists, 61 or about 95 per cent of the graduate dentists, 14 physical education students, 8 graduate students in education, and 2 students specializing in speech. A definite and significant impression has been received that each of these students completed the course with a feeling that there was something that he or she could contribute in an attempt to improve the nutrition of the public.

It is not considered desirable to attempt to make nutrition specialists out of these people. Rather, the intention is to provide each of them with a broad understanding of the relation of food to total health and social welfare. This, it is hoped, will serve not only as a framework upon which they may add new developments in the science of nutrition, but also as a basis for applying that knowledge to the solution of the feeding problems of human communities. The degree to which this is accomplished will influence the service of public health agencies to mankind.

Y.M.C.A. Local Health Units Resolution

The National Physical Education Committee of the Y.M.C.A. at its quarterly meeting in January adopted the following resolution submitted by the Committee on National Relationships:

Be it resolved that the National Physical Education Committee in its formal and informal relationships with area councils, state committees, and local Associations, use its good offices and official connections to encourage local Associations to participate actively in local community health councils or other organized bodies interested in promoting the general health of the community. Further, if no health council or similar organization exists in a community where the Y.M.C.A. is operating, that the Association initiate steps which would make for the formation of community health council.

And, the National Physical Education Committee recommends that all area councils and state Y.M.C.A. committees become acquainted with the work of state health councils and affiliate if desirable with such state health agencies so that Y.M.C.A.'s of the state or area may be benefited by being able to avail themselves of the resources of literature, exhibits, films, and personnel of the state health agencies, and likewise, give such help as they can as official representatives of the Y.M.C.A.'s of the state in furthering the general health.

And further, be it resolved that in so far as practicable, the Senior Secretary for Physical Education of the National Board, Y.M.C.A.'s, will advise and assist area and state Y.M.C.A. committees in organization efforts, in developing continuing program ideas and in providing such printed material as can be secured without cost from public and private health organizations,

And finally, be it resolved that the National Physical Education Committee encourage careful study and coöperate efforts by area and state Committees and local Associations in the development of effective "local health units" as currently proposed by the National Health Council and its National Advisory Committee on *Local Health Units*; such units to make possible a higher level and more even provision of health education and health services throughout the country.

Training Physicians in Public Health Nutrition*†

FREDRICK J. STARE, M.D., F.A.P.H.A.

Department of Nutrition, Harvard School of Public Health, Department of Biological Chemistry, Harvard Medical School, Boston, Mass.

TRAINING physicians for work in the field of public health nutrition is a problem of current importance because, of all the environmental factors affecting health in present-day civilization in this country, none is more important than nutrition. The first half of this century has witnessed a great improvement in public health, due largely to the control of infectious disease. Tuberculosis, pneumonia, and dysentery, which were the leading causes of death in 1900, are no longer major public health problems. We know how to control these diseases; all that remains is a "mopping up procedure." It would seem that the professional health school which concentrates on sanitation and the control of communicable disease is simply resting on the laurels of the past. The health problems which confront us in the last half of the 20th century are the degenerative diseases, particularly cardiovascular-renal disease and cancer. Advances in this area will be aided by increased knowledge of cellular nutrition. A less clearly defined problem, but nevertheless an important one, is the overall improvement of well-being as evidenced by healthier children and a more productive life for adults. This problem includes the preventive aspects of illness, both physical and mental, and better nutrition will play an important part in its solution. Too many of the current leaders in medicine and public health still think that three meals a day which satisfy the appetite will provide adequate nutrition. Nothing could be farther from the truth.

Nutrition, or the science of food and its relation to health, is a comparatively new field. The daily diet with the economic problems relating to obtaining it, is an old and familiar one. The investigator in the laboratory with his knowledge of how to better nutrition, and the health worker with his knowledge of human needs have been far apart. If the information obtained by the investigator is to be applied by the health worker, this distance must be bridged. The investigator is primarily responsible for getting information, the health worker primarily for interpreting it. The distance between them can be decreased by bringing the results of investigation to the health worker by means of a thorough professional training.

It should be emphasized that there is a severe shortage of professional workers with special training in foods and nutrition. Few physicians, health officers, dentists, medical or health administra-

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

† This paper includes material from a report (Sept., 1946) of a committee appointed by the Dean of the Harvard Medical School to make recommendations on the teaching of nutrition to medical students and from a report (May, 1948) of a committee of the Nutrition Section of the National Health Assembly appointed for the purpose of making recommendations concerning the teaching of nutrition to medical, dental, and health personnel. The author was chairman of these two committees.

tors, nurses, or social workers have received much training in this field. This situation indicates the need for an evaluation of the academic requirements for personnel specialized in nutrition and of the important economic and social problems of salaries, working conditions, and professional prestige.

SPECIFIC TRAINING PROPOSALS

There is one general condition that applies in varying degree to all categories of professional workers, namely an adequate basic training. Nutrition, as a science, is a development largely of biochemisty which in turn is an outgrowth of chemistry and physiology. Therefore, all the professional workers in the field of nutrition should have some acquaintance with general chemistry, physiology, and biochemistry, the amount depending on what the professional worker is to do. Obviously, the investigator in the nutrition laboratory needs far more preparation in basic science than does the practising or public health physician, but a good principle is that no one will make a serious mistake by emphasizing training in the basic sciences. The facts of human nutrition have come mainly from two sources, the laboratory experiment and observations of the food practices and nutritional condition of individuals and of peoples. Since nutrition is an experimental science, it is important that professional workers should have an appreciation of the experimental method acquired through experience in the laboratory. On the other hand, there are aspects of nutrition which are treated by the social sciences and the physician who does not understand this interrelation will remain permanently handicapped in his effort to adjust food practices to nutritional needs.

Any discussion of training physicians for work in public health nutrition should really begin with a brief discussion of training physicians in nutrition. The following recommendations are general and should be modified according to individual circumstances.

Medical Undergraduates—

In medicine, as in public health, the applications of nutrition are so broad that training can be had best along two main lines: first, incorporating nutrition in many of the courses standard in present curricula; and second, adding special courses for those students who are particularly interested in nutrition, or some aspect of nutrition as a specialty. Integration of nutrition teaching in a professional school can be accomplished only if some individual, or a special committee, is made responsible for planning and implementing this teaching program.

Nutrition should be an essential component of the standard medical curriculum, but in general should be incorporated into standard courses. The following outline suggests how various aspects of nutrition can be fitted into the medical curriculum:

COURSES OF THE FIRST AND SECOND YEARS

Anatomy—The effects of exogenous and environmental stimuli, many of which are nutrients, on cell structure, growth, and function should be discussed.

Biochemistry—

A. General lectures in biochemistry dealing with protein, fat, carbohydrate, minerals, and water balance

B. Specific lectures dealing with nutrition as follows:

1. Historical—Present Concept of Nutrition
2. Vitamins A and D
3. Thiamine, Riboflavin, and Niacin
4. Folic Acid, Choline, and Ascorbic Acid
5. Other Vitamins and Growth Factors
6. Trace Minerals in Nutrition
7. Nutrition in Medicine

C. Laboratory work in experimental nutrition

Physiology—The physiology of digestion and metabolism should be thoroughly covered, with special attention to nutritional factors.

Bacteriology—Lectures covering the material suggested by the following titles:

1. Bacterial Nutrition
2. Bacterial Nutrition and Its Relation to Chemotherapy and to the Study of Nutritional Problems in Man

Pathology—The pathology of nutritional deficiencies should be thoroughly covered.

Physical Diagnosis or Second-Year Medicine—Periods covering material included in the following titles:

1. Symptoms and Signs that May Be Associated with Inadequate Nutrition
2. The Classical Nutritional Deficiencies

Laboratory Diagnosis—Laboratory methods in the diagnosis of nutritional deficiencies should be discussed.

Second-Year Pediatrics—Courses dealing with growth, development, and maturation should include the following:

1. Nutrition and the Physiology of the Newborn
2. Nutrition and the Progress of Growth
3. Nutrition and the Significance of Retarded Growth
4. Nutritional Requirements of Infants and Children and How These Requirements are Met by Food.

COURSES OF THE THIRD AND FOURTH YEARS

Third-Year Lectures in Medicine or Surgery—

1. Evaluation of Nutritional Status
2. Nutritional Problems in General Medicine
3. Conditioned Nutritional Deficiencies
4. Obesity and Malnutrition
5. Calcium and Phosphorous Metabolism
6. Nutrition in Convalescence
7. The Use and Abuse of Commercial Vitamin, Mineral, and Protein Preparations
8. Supplementary Feedings—Oral, Tube, and Parenteral

Third-Year Lectures in Pediatrics—Courses dealing with principles of infant and child feeding should include considerations of:

1. Acute and Chronic Deficiencies, e.g., Rickets, Scurvey, Tetany, Anemias, etc.
2. Interrelationships between Nutritional Deficiencies and Infectious Diseases in Failure of Growth and Development

Third-Year Lectures in Obstetrics: Lectures covering the material suggested by the following titles should be given:

1. Nutritional Requirements in Pregnancy and Lactation and the Importance of Breast Feeding
2. Nutrition and Its Relation to Complications of Pregnancy and the Health of the New-born

Third-Year Lectures in Preventive Medicine—Lectures covering the material suggested by the following titles:

1. Nutrition and Improved Health
2. Nutritional Studies of Population Groups
3. Nutrition and World Economics

APPLIED NUTRITION (DIETETICS)

As part of the outpatient or ward service in medicine, surgery, obstetrics, and pediatrics, sufficient time should be made available for each student to become thoroughly familiar with the principles of applied nutrition. Each student should be able to write dietary prescriptions which will provide for adequate nutrition, and to interpret them in terms of food. This can be taught best by a competent therapeutic dietitian working with groups of 6 to 8 students, and would require a minimum of three 2 hour periods. It makes no difference whether this is taught on the medical or surgical service. Applied nutrition in obstetrics and pediatrics should each be considered separately and would each require two 2 hour periods providing the students have already had the basic instruction in applied nutrition recommended for medicine and surgery, and if this is not the case, a third 2 hour period would be needed.

"Nutrition Rounds"—Once a week a member of the clinical staff in medicine, surgery, pediatrics, and obstetrics may see with the students on the service, patients who present unusual or common nutritional problems. The therapeutic dietitian should accompany the group on rounds and participate in the discussions.

The weekly clinical-pathologic conference and the weekly grand rounds held by most hospitals are valuable teaching aids. Discussions on various aspects of nutrition should be organized on appropriate occasions.

Socio-economic Factors in Nutrition—In any discussion of applied nutrition, the medical student, as well as other professional health personnel, must consider the socio-economic factors of obtaining the food necessary for any recommended diet. How does the patient get the money (or the food) for diets that are prescribed? The participation of the medical-social worker in case conferences will help both students and doctors to recognize and solve these important problems.

Physicians in Public Health Work—Some health personnel have the opportunity to attend a school of public health. This is a highly desirable procedure. Health personnel who do not attend a graduate school for training in public health must rely on undergraduate training as already mentioned, and on their own initiative to keep up to date with advances in nutrition that apply to public health.

Every health officer who holds, or hopes to hold an important administrative post in public health, and who attends a graduate school of public health, should have a course under a title such as "Public Health Nutrition." The same or a similar course is needed in the training of public health nurses and health educators. Such a course should consider the following subjects. These can be adequately covered in a series of twenty-four 1 hour lectures.

1. A brief review of fundamental principles of nutrition
2. Application of the science of nutrition to human nutrition
   a. Dietary requirements of growth, pregnancy, lactation, and adulthood and how they can be met by foods
   b. Diet in relation to dental structures
   c. Diet in the treatment of disease
3. Establishment of minimum and optional nutritional allowances
   a. Fulfilling allowances in terms of foods, especially with reference to low income levels
4. Methods for evaluating nutritional status
   a. Biochemical and physical examinations
   b. Nutritional histories; food intake studies
   c. Surveys of population groups
5. Nutritional deficiency diseases
6. Factors affecting food values: processing, cooking; enrichment and fortification
7. Factors affecting food habits: cultural, economic, psychological
8. Nutrition services as part of the public health program: national, state, community
   a. Organization and fields to be covered
      (1) The place of the nutritionist
      (2) Coördination of program with other community services and organizations
      (3) The school lunch; industrial feeding
9. Nutrition and world health
   a. Problems of the production and distribution of food
   b. Relief, rehabilitation famine, and other emergencies

In a school of public health the administrative and epidemiological aspects of public health nutrition might best be taught conjointly with the departments of administration and epidemiology. The important thing is to see that these approaches are not omitted.

Health officers who are interested in securing more information on nutrition than already suggested should participate in seminars, discussion groups, and journal clubs. Suggested topics for special seminars are the following:

1. The administrative organization of nutrition in the health department
2. Nutrition services in the health department
3. Recent nutrition research and its importance to public health problems
4. Social and cultural patterns and their importance in public health nutrition
5. International nutrition and the problem of food supplies and population trends.

SUMMARY

Nutrition is such a broad and important subject in health that all health personnel should have some awareness of the subject. This applies particularly to the physician in public health work. Professional training in nutrition is important and, depending upon

Bacteriology—Lectures covering the material suggested by the following titles:

APPLIED NUTRITION (DIETETICS)

As part of the outpatient or ward service in medicine, surgery, obstetrics, and pediatrics, sufficient time should be made available for each student to become thoroughly familiar with the principles of applied nutrition. Each student should be able to write dietary prescriptions which will provide for adequate nutrition, and to interpret them in terms of food. This can be taught best by a competent therapeutic dietitian working with groups of 6 to 8 students, and would require a minimum of three 2 hour periods. It makes no difference whether this is taught on the medical or surgical service. Applied nutrition in obstetrics and pediatrics should each be considered separately and would each require two 2 hour periods providing the students have already had the basic instruction in applied nutrition recommended for medicine and surgery, and if this is not the case, a third 2 hour period would be needed.

"Nutrition Rounds"—Once a week a member of the clinical staff in medicine, surgery, pediatrics, and obstetrics may see with the students on the service, patients who present unusual or common nutritional problems. The therapeutic dietitian should accompany the group on rounds and participate in the discussions.

The weekly clinical-pathologic conference and the weekly grand rounds held by most hospitals are valuable teaching aids. Discussions on various aspects of nutrition should be organized on appropriate occasions.

Socio-economic Factors in Nutrition—In any discussion of applied nutrition, the medical student, as well as other professional health personnel, must consider the socio-economic factors of obtaining the food necessary for any recommended diet. How does the patient get the money (or the food) for diets that are prescribed? The participation of the medical-social worker in case conferences will help both students and doctors to recognize and solve these important problems.

Physicians in Public Health Work—Some health personnel have the opportunity to attend a school of public health. This is a highly desirable procedure. Health personnel who do not attend a graduate school for training in public health must rely on undergraduate training as already mentioned, and on their own initiative to keep up to date with advances in nutrition that apply to public health.

Every health officer who holds, or hopes to hold an important administrative post in public health, and who attends a graduate school of public health, should have a course under a title such as "Public Health Nutrition." The same or a similar course is needed in the training of public health nurses and health educators. Such a course should consider the following subjects. These can be adequately covered in a series of twenty-four 1 hour lectures.

1. A brief review of fundamental principles of nutrition
2. Application of the science of nutrition to human nutrition
   a. Dietary requirements of growth, pregnancy, lactation, and adulthood and how they can be met by foods
   b. Diet in relation to dental structures
   c. Diet in the treatment of disease
3. Establishment of minimum and optional nutritional allowances
   a. Fulfilling allowances in terms of foods, especially with reference to low income levels
4. Methods for evaluating nutritional status
   a. Biochemical and physical examinations
   b. Nutritional histories; food intake studies
   c. Surveys of population groups
5. Nutritional deficiency diseases
6. Factors affecting food values: processing, cooking; enrichment and fortification
7. Factors affecting food habits: cultural, economic, psychological
8. Nutrition services as part of the public health program: national, state, community
   a. Organization and fields to be covered
      (1) The place of the nutritionist
      (2) Coördination of program with other community services and organizations
      (3) The school lunch; industrial feeding
9. Nutrition and world health
   a. Problems of the production and distribution of food
   b. Relief, rehabilitation famine, and other emergencies

In a school of public health the administrative and epidemiological aspects of public health nutrition might best be taught conjointly with the departments of administration and epidemiology. The important thing is to see that these approaches are not omitted.

Health officers who are interested in securing more information on nutrition than already suggested should participate in seminars, discussion groups, and journal clubs. Suggested topics for special seminars are the following:

1. The administrative organization of nutrition in the health department
2. Nutrition services in the health department
3. Recent nutrition research and its importance to public health problems
4. Social and cultural patterns and their importance in public health nutrition
5. International nutrition and the problem of food supplies and population trends.

SUMMARY

Nutrition is such a broad and important subject in health that all health personnel should have some awareness of the subject. This applies particularly to the physician in public health work. Professional training in nutrition is important and, depending upon

the profession, should include some or all of the following:

1. Basic and historical information on the science of nutrition, in perspective to the other sciences
2. Applications of nutrition to medical and health problems
3. An account of recent research in nutrition as it applies to public health with some evaluation of present and future problems
4. The economic, social, and psychologic aspects of nutrition

Professional training in nutrition should be given by each of the following general procedures:

1. Instruction in nutrition should be given in each of the years of professional schooling.
2. Most of this instruction should be incorporated in standard courses of the curriculum.
3. Special courses in public health nutrition should be given in schools of public health.

CONCLUSION

In conclusion, may I repeat the opening sentence of this paper—"Training physicians for work in the field of public health nutrition is a problem of current importance, because of all the environmental factors affecting health in present-day civilization in this country, none is more important than nutrition."

Foreign Teaching Opportunities Under U. S. Fulbright Act

The U. S. Department of State has announced an opening under the Fulbright program for a visiting professor in public health at the Medical College, University of Rangoon, Burma, for one academic year beginning in June, 1949. According to the announcement, persons interested in the opening should have had extensive experience in public health activities in rural and warm-climate areas, should have an M.D. degree, and should possess the personal qualifications necessary for advising on large scale problems. The award will be made in Burmese currency and includes stipend, a maintenance allowance, round-trip transportation, and an allowance for books or equipment necessary to the teaching assignment. Requests for further information should be addressed to the Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Avenue, Washington 25, D. C.

The Fulbright Act (Public Law No. 584, 79th Congress, Second Session) authorizes the U. S. Secretary of State to set aside a portion of the foreign currencies resulting from the sale of surplus property abroad for educational exchange programs with certain foreign governments. It is understood that the Fulbright program is still in its initial stages and that policy decisions are in the process of formulation. Stipends, however, are expected to bear a reasonable relation to the grantee's salary and in addition, allowances may be provided for housing and cost of living. Transportation for grantees from and to the United States may be provided in addition to the total award when the foreign currency is acceptable to the carriers. Transportation inside the United States will not be provided.

Public Health Engineering in Foreign Areas with American Industry*

JOHN M. HENDERSON, C.E., F.A.P.H.A.

Professor of Sanitary Science, Columbia University School of Public Health, New York, N. Y.

THE revolutionary changes in the peacetime foreign policy of the United States that have taken place during the past 3 years are apparent to all. Military and temporary economic rehabilitation aspects however have tended to distract attention from long-range economic factors, including the expanding role of American production in foreign areas. This expansion results from two fundamental conditions.

The first might be termed the strategic materials situation. One phase of this is the ever growing list of materials, especially minerals, which are vital both to our increasingly complex industrial civilization and to national defense. In terms of national defense alone, at least 70 strategic materials either are not present in the United States or are rare. They may be exemplified by radioactive minerals. The other phase is the growing scarcity of our resources of ores and petroleum. In some cases this is relative—arising primarily from increasing demand; in others it is absolute—due to the actual or impending exhaustion of all but low grade deposits. Our present economy requires natural resources that are not only abundant but relatively inexpensive to process. The depletion of American iron ores, for example, may warrant main reliance on high grade foreign sources in preference to domestic low grade deposits, as is the present case with bauxite.

The second fundamental condition is related to the decline of the British Empire in world affairs and to a closer working relationship between the United States and Britain. The extensiveness of British interests and, to a lesser extent, those of the Netherlands, Belgium, and France in the rich raw materials areas of the world, particularly in the eastern hemisphere, is only dimly realized by most Americans.

The vacuum created in these areas by European weaknesses is not confined to questions of political and military strategy but extends into the economic domain. The world economy is so interrelated that American industry and American enterprise must fill this breach if world recovery is to be realized and the well-being of this country maintained.

The mere engagement of American companies in agricultural or industrial source production outside of this country and its possessions of course is not a new phenomenon. The United Fruit Company for one offers notable example of long established activity in this direction. What is significant is the changing status from the exceptional to the commonplace, the great increase in scale and the necessity for locating many developments in the more disease-ridden parts of the world.

These factors are exemplified by the

American oil industry which may be considered as a forerunner in the current epoch of foreign expansion. According to available data, 23 principal American oil companies are engaged in petroleum development and production in 22 foreign countries. These companies are listed by name in Table 1. The countries involved are given in Table 2. This list would be much longer if it included non-producing areas in which American oil exploration is under way, some of which may be rich fields in the future. In still other countries American oil companies have purchasing agreements with foreign companies, or are involved in joint pipe line or refining ventures.

The volume of production and size of oil company populations in the countries listed cover a wide range. The great oil producing area of the future is, of course, the Middle East; provided the foreign policies of the United States and other countries permit. One American company alone has budgeted $1,300,000,000 for expansion in this area. Current and developing production from this region not only serves as a foundation for European recovery, but indirectly provides gasoline and oil for American automobiles, homes and industries. From the world's leading exporter of oil, the United States has shifted to a position of net importation. Oil from Venezuela that formerly went to Europe is now being increasingly diverted here as rapidly as expansion of Middle East exportation to Europe permits. Venezuela ranks second among foreign countries in proven resources. American oil producers have been long

established there and production is still expanding.

Our major expansion in foreign oil enterprises and potentially in other areas of production poses problems in which the public health profession and industry have important joint responsibilities.

In the field of public health these rest most directly on public health engineering and tropical medical groups, related to climatic and geographic location, and character of disease problems.

Unlike the relatively dispersed or marginal problems of environmental disease incidence encountered in the United States today, the prevention and reduction of the principal endemic and epidemic diseases in these areas are dominantly responsive to sanitation measures. Their medical epidemiology and clinical treatment are within the scope of tropical medicine.

As regards sanitation, there is reassuring evidence that American oil industry at least is aware of the problem. One manifestation has been its interest in recruiting public health engineers for resident foreign service and in obtaining advice on sanitation matters. While such foreign employment will always be minor in magnitude by comparison with public health engineering positions in this country, the medical department of one subsidiary operating company in Venezuela has a staff of 8 public health engineers. Another manifestation is the willingness to make heavy investment in the planning, construction, and operation of permanent modern facilities for living comfort and health, including sanitary utilities, housing and recreational facilities. American experience during the past war, which demonstrated the effectiveness with which sanitary safeguards can be applied to protect imported personnel from local disease in isolated parts of the world, has helped to make American management in foreign areas intolerant of the more complacent attitudes of their European associates and competitors. Experience in military service and the high sanitary standards in this country by comparison with those of other nations lead the American worker in foreign areas to insist upon adequate health protection.

While there is willingness in principle on the part of management to adopt optimum programs of sanitation, some weaknesses in execution exist; correction of which requires joint action by industry, public health, and schools for professional training.

First, there is a dearth of available and suitable personnel for sanitation services and other related activities. A basic cause is the lack of a career tradition of foreign service in this country, which is most acutely evident to those familiar with the functioning of the British Empire and British private enterprise in foreign lands. Since the days of Horace Greeley and the winning of the West, Americans have largely reverted to a status of geographical insularism in an occupational sense. When we do reside in foreign lands, we are too often patronizing, and insular in viewpoint and environment. This general situation perhaps offers the greatest single threat to the successful fulfillment of American foreign needs in all quarters. Such insularity is especially misplaced for American public health engineers and other sanitarians, medical and non-medical, in view of the pioneering opportunities and needs in foreign areas in this field.

In a previous article [1] it was suggested that professional malaria control workers in the United States might well seek employment in other lands or change or broaden their specialty. The need for such choice does not exist among those otherwise engaged in environmental sanitation here, but foreign service is suggested either as a permanent career, or less permanently to accelerate the gaining of a professional maturity and competency in the practice

of public health engineering in this country. The attractive salaries offered for many foreign service assignments also should not be ignored. Parenthetically, it might be noted that the scarcity of American public health engineers in pioneering foreign service was so great before the war that the general practice of tropical sanitation in some countries is still viewed as a field restricted to the medical officer and occasionally the entomologist. This reflects not merely past lack of opportunity for public health engineering employment in foreign areas, but, by comparison with medical and other biological scientists, a lack of zeal for field service under unattractive living conditions and often with little financial compensation. It is hoped that this attitude will not continue under the changed conditions of today.

The second basic factor pertains to qualification for the position. Consideration of this requires an understanding of programs and problems. The administrative pattern of sanitation programs varies with different companies and may be subdivided into two main categories: (a) division of responsibility and functions between the engineering or public works department, and the medical department, and (b) sole responsibility by the engineering department except for medical advice. Which pattern is adopted depends in part on whether sanitation is carried on only in company areas or whether outside national populations are also being served. In either case, the sanitation program is characteristically operational, involving the direct management and execution of sanitation measures.

In the second place, the major activities of the sanitary organization are more varied and comprehensive than in this country. To mention only a few fields of sanitation, the fly, the mosquito, or both, almost without exception constitute major problems of disease incidence, or at least hazard, in tropical oil installations. Other arthropods and rodents commonly are important as well. Food problems become far more difficult and complex where temperatures are high and native food handlers are employed. At the same time, resourcefulness in the management and operation of water supply and sewerage systems is made necessary by unusual technical problems, remoteness from source of supplies and equipment, and an unreliable labor force. Extensive investigational services to define the problem and basic developmental research preceding control are required.

In one Middle Eastern installation for example, direct sanitary operations on company property encompass water supply, sewerage, solid wastes, housing and ventilation, swimming pools, bathing places, control of flies, rats, mice, and roaches. I repeat, these are operational, not technical supervisory, responsibilities. Supervisory functions include industrial messes served by East Indian food handlers, ice and bottling plants, a bakery, and occupational sanitation. Fly production is far too great for effective suppression by DDT residual house spraying alone, and is responsible for a high incidence of dysentery and gastroenteritis via food, and of trachoma. The bionomics of desert flies differ greatly from those in this country and knowledge of their habits is scanty. Sources of food supply include native meats and sometimes native vegetables from night soil gardens. The present temporary water supply is turbid surface water, chlorinated but unfiltered, obtained from a watershed where bacillary and amebic dysentery and schistosomiasis are highly prevalent. The importation of plague-infected fleas and rats and of cholera-laden flies by ship and aircraft from relatively nearby endemic sources must be constantly guarded against. An adjoining area has hyper-endemic malaria and local plans for irrigation may

introduce a pressing hazard of importation and establishment of anopheline and other mosquito species.

The installation is remote and the sanitary organization must be a self-contained task force prepared to cope with all problems promptly and effectively. The engineering director and staff must possess a high order of managerial and scientific abilities spread over a wide range of sanitation fields, and aptitude for training local personnel.

At the present time, the principal avenues of employment for sanitary or public health engineers in this country are in operational assignments with municipal departments other than the health department, or on other types of assignments with health agencies. The non-health department engineer usually possesses operating experience, but this seldom extends beyond water, sewerage, and solid wastes, and is more commonly confined to only one of these. The engineer with the health department generally has a greater breadth of experience in terms of fields of sanitation, but this is apt to be limited to non-managerial aspects.

In view of the above, it is apparent that industrial employers are under substantial handicaps in selecting proper personnel. The importance of selecting the right personnel cannot be overstressed, because of the responsibilities at stake. In addition to the basic value of preventing death and illness per se, the economic case for top notch operations in sanitary services is strong. During the war it was demonstrated in tropical areas that heavy expenditures for such measures were quickly paid for by the mere cancellation of ambitious plans for enlarged hospital facilities and staffs occasioned by abnormal illness rates. In the Middle East the reputed cost of bringing a single oil worker from the states and returning him is $3,000. While greatest reduction in personnel turnover can be realized by eliminating preventable disease, it can be reduced further by providing a clean, comfortable environment obtained by prosecuting additional sanitation measures not required for the actual reduction of disease.

Another significant reason for obtaining sanitation personnel competent to do the job lies in the need to sell management on the benefits of an effective sanitation program. Oil industry executives are trained in oil production, not public health engineering. Appreciation of sanitation needs tends to be sympathetic but exoteric and qualitative, whereas appreciation of need for geologists for example, is precise and quantitative. (Of course, we public health workers in their positions would need to acquire an appreciation of geological requirements.) A successful demonstration, efficiently conducted and effective in results, is the best answer to such situations.

There is no easy solution to this personnel situation. On the part of industry two steps are indicated. First, it should seek public health engineering counsel in this country in making personnel selections. Such inquiries should extend beyond writing the usual references supplied by the applicant and should be made of impartial advisers with broad vision and a practical understanding of tropical sanitation problems and programs. That is, hand-picked recruitment is called for.

Second, there is evident need for the oil industry and others operating in tropical areas to underwrite on a modest scale facilities in this country for training and research in tropical sanitation, i.e., the tropical practice of public health engineering. Such action would seem to be more within the province of an industry-wide association, such as the American Petroleum Institute, than of the individual company. The National Sanitation Foundation, as jointly established by the food industry and the

University of Michigan School of Public Health for progress in the field of food sanitation in this country, is an excellent example of this type of enterprise.

In addition to serving as a center for technical information, field research, and consultation, this Tropical Sanitation Foundation would provide special, select postgraduate training in tropical sanitation to engineers, entomologists, veterinarians, and other professional sanitarians; thus paralleling existing facilities in tropical medical training. Such training would be primarily concerned with filling special gaps in the professional knowledge of persons preselected for foreign assignment and already possessing basic professional training and proven ability in field operations and management. For the engineer in particular, it would attempt to bridge the gaps between: (1) the sanitary engineer in municipal management, (2) health department engineering, and (3) tropical sanitation.

The author is well aware that some graduate professional schools in this country, including his own and its affiliate, the School of Tropical Medicine in Puerto Rico, offer courses in tropical sanitation adjunctive to other engineering and medical training. He is equally aware that such training cannot satisfy the need described until it becomes a distinct entity, adequately financed and staffed with faculty members dedicated to this single task and possessing an understanding of the psychologic and philosophic, as well as technologic, differences between tropical and domestic sanitation, and between operations as compared with so-called technical supervision. Although the training would be primarily engineering in character, special consideration would be given to the sanitary entomologist, and to the engineering-entomologist-biologist team concept in the control of animate non-human vectors of disease. This training would be equally apropos for such individuals employed in tropical service by government.

On the part of the public health profession there is needed first a developing tradition and interest in foreign career service, as discussed previously. Beyond and allied to this is needed a sense of national responsibility and of obligation for service in a field of activity which underpins success in a vital national interest. Third, there is needed a better understanding of the nature of the work and a desire on the part of those interested in foreign service to prepare themselves for the effective professional practice of tropical sanitation.

In its inter-American aspects, the picture cannot be considered complete without mentioning the constructive value of the Pan American Sanitary Bureau, the Inter-American Association of Sanitary Engineering, and the Institute of Inter-American Affairs in advancing the general cause of tropical sanitation. The Institute has direct relationships to the problems discussed in this article. It has provided invaluable field experience to public health engineers who subsequently have been employed by industry, and has strengthened governmental sanitation services in tropical areas. The programs of all three organizations might well benefit from the activities of a tropical sanitation foundation dedicated to training and research in all applications of tropical sanitation.

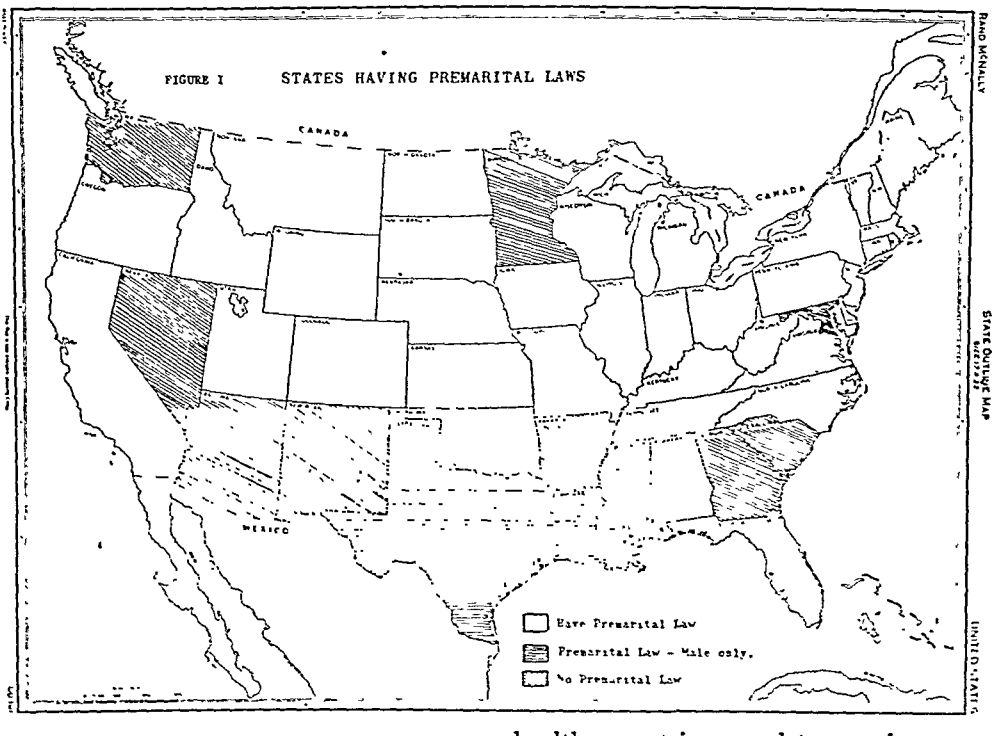
Interstate Reciprocity for Approved Laboratories*



WILLIAM LEVIN, DR.P.H., F.A.P.H.A.

Director State Hygienic Laboratory, Portland, Ore.

PUBLIC acceptance of premarital examinations, both physical and laboratory, has been truly amazing. Many of us can remember the time when the only difficulty in getting married was to obtain the consent of the girl in question or possibly find the fee for the license and minister. Today the steps to the altar, although following the pattern of the past, are a little more tortuous. By public demand, 36 states now require a physical examination, including a blood test for syphilis as a prerequisite for the marriage certificate; 2 other states require the male applicant alone to be examined; 10 states have no prenuptial examination requirements. It may confidently be expected that the coming generation will find all states demanding evidence of freedom from infection before a marriage certificate is issued. Getting married now is a serious proposition, which is as it should be.

The first attempt to inject a public health aspect in regard to marriage was made by the State of Washington in 1909; it was short lived, as the law

FIGURE 1 STATES HAVING PREMARITAL LAWS

* Presented at the Annual Meeting of the Western Branch American Public Health Association in Salt Lake City, Utah, May 27, 1948.

was repealed in 1910. In 1913 the States of North Dakota, Oregon, and Wisconsin passed premarital laws applicable to male partners only. Alabama in 1919, North Carolina and Wyoming in 1921, Louisiana in 1924, and Texas in 1929 also approved premarital legislation. In no state, however, was a laboratory test required. The first acceptable law from the public health viewpoint was that adopted by Connecticut in 1935, which required both applicants for the marriage license to submit to blood tests for syphilis. In addition, a penalty was imposed upon any clerk who issued a license without a statement by a licensed physician certifying to freedom from syphilis both by examination and laboratory test. With the exception of Louisiana and Texas, all states having premarital laws now require both applicants to submit to blood tests for syphilis, and the certification by a regularly licensed physician that they are free from syphilis or communicable syphilis. Infectious tuberculosis is a bar to marriage in North Carolina and Rhode Island. Epilepsy and several forms of mental ailments will prevent marriage in North Carolina and Oregon. Oregon has gone all out, eugenically speaking, by refusing certificates if drug addiction or chronic alcoholism can be demonstrated.

If both applicants for a marriage license reside within the same state and intend to be married within that state, then the laboratory procedure is simple. The physician obtains the blood specimens, submits them to the laboratory of the state department of health, or to any of its branch laboratories, or to laboratories approved by the state department of health. Upon receipt of the laboratory report the physician then makes the required certification as to absence of infection. The applicants then proceed with the physician's certificate to the office of the county clerk or other officer designated by law to issue marriage licenses, and when the waiting period (if any) has been complied with, the licenses are then issued.

Should, however, either or both of the applicants reside in a state other than the one in which the marriage ceremony is to take place, the procedure becomes somewhat more complicated. If the premarital laboratory tests are made in their own states, the reports may be unacceptable. Even if acceptable, their home physician certifying them may not be licensed to practice in the state in which the marriage is to take place. Then again, assuming reports from the home laboratory and certification by the physician acceptable, the forms on which the reports and certification are made may be unacceptable. The lack of uniformity in requirements for out-of-state premarital applicants is striking, utterly confusing, and to the persons concerned, a violent headache.

The confusion caused by a lack of reciprocity in premarital laboratory tests performed in other states was discussed by Forster and Shaughnessy in 1942, in an informative article published in the *Journal of the American Medical Association*. They concluded that: "the establishment of reasonably uniform requirements and procedures for interstate marriages is a goal which should be reached as quickly as legal and administrative barriers can be surmounted." At the 1946 Conference of State and Provincial Public Health Laboratory Directors a report was presented on Serological Tests for Syphilis by the Subcommittee of the Committee on Evaluation and Approval of Laboratories, in which the question of acceptance of results from out-of-state laboratories was gone into in detail and a number of recommendations were made. Had these been adopted, they would have gone far to bring order out of chaos. The committee recognized "that premarital laws have considerable merit, and also feels that unless some of these problems

can be handled with less inconvenience to the public than has occurred in the past, that such laws may be jeopardized in some states."

The comparative rapidity with which states adopted premarital legislation indicates a recognition of its value in social prophylaxis. The discovery of new or latent cases of syphilitic infection, frequently unknown to exist to the victims themselves, is a matter of record in all states requiring premarital serologic tests for syphilis. Table 1 shows the number of positive, doubtful, and negative serologic findings among marriage applicants in Oregon in the past five years. These figures are on specimens examined in the State Hygienic Laboratory alone:

TABLE 1

Results of Premarital Serology Tests 1943–1947

	1943		1944		1945		1946		1947	
	No.	%	No	%	No	%	No.	%	No.	%
Positive	13	0 68	25	1 06	37	0 97	60	0 98	80	1 09
Doubtful	5	0 36	19	0 81	25	0 66	42	0 69	64	0 88
Negative	1,892	98 96	2,307	98 13	3,747	98 37	5,992	98 33	7,142	98 03
Total	1,910	100 00	2,351	100 00	3,809	100 00	6,094	100 00	7,286	100 00

The precentages are approximate, since some of the positive and doubtful results were obtained on repeat specimens. For the 5 year period 1943–1947, approximately 1 per cent of the applicants gave a positive serologic test for syphilis. These figures indicate the value of the premarital laboratory test in venereal disease control. Certainly nothing should be done to jeopardize or even to impede its continuance.

Without exception the reports of serologic tests for syphilis made in a state department of health laboratory are accepted by all other states. Some states also recognize branch laboratories of state health departments and laboratories operated by the Army, Navy, and the Public Health Service. Sending the blood specimens of an out-of-state marriage applicant to his own state laboratory, therefore, would seem to be the logical procedure. What is logical, however, may not always be most expedient. There are two classes of people who enter into the state of matrimony: those who are deliberate and those who are impetuous. Occasionally the most deliberate of deliberates will become the most impetuous, and a delay of a day or two in the marriage ceremony would seem to be the most tragic event in their lives.

To out-of-state marriage applicants, nevertheless, the question of time is particularly important, and rightfully so. Many legitimate reasons enter into the necessity of obtaining a marriage certificate in the shortest possible time. Specimens which are delayed in transit, hemolyzed or otherwise unsatisfactory, cause delay in the receipt of the laboratory report and thereby may upset a carefully planned schedule and ultimately even postpone the wedding ceremony. To prevent such occurrences and to make local laboratory facilities available, most state departments of health have approved laboratories for the performing of required tests for premarital applicants.

In the vast majority of states the responsibility of approval of laboratories has been left to the state department of health or to the state health officer. Frequently, as in our state, advisory boards have been set up to assist in formulating standards and in recommending approval. In Oregon approval is granted after satisfactory compliance with the following requirements:

a. Evidence of proper training and experience of personnel
b. Adequate facilities and equipment, as shown by inspection
c. Satisfactory performance of serologic tests for syphilis and smear examination for gonococci on at least 50 blood specimens and 10 smears sent by the State Hygienic Laboratory

With minor modifications (and they usually are concerned with the number of specimens examined) these are the requirements set up by the various state departments of health in approval of laboratories within their own states.

A questionnaire was sent to each state asking, among other things, whether it would desire to enter into a reciprocity agreement with Oregon in the acceptance of reports from approved laboratories, assuming that its standards were at least equal to those of Oregon. The following replies were received:

Would enter into reciprocity agreement	14
Would not enter into such agreement	21
Would accept reciprocity conditionally	1
No opinion	2

Eleven states* now accept out-of-state reports from laboratories approved by their respective departments of health. Several of these require certification of the report by the state health department. The Oregon State Board of Health has gone on record as desirous of accepting out-of-state reports from approved laboratories provided the standards of approval are at least equal to those of Oregon. We have had reciprocity with California for nearly a year and it has worked to the advantage of both states. At the present time we approve laboratories for a calendar year, the certificate expiring December 31. Laboratories failing to make the grade or new laboratories desiring approval, are examined in June, and if found satisfactory, are certified for the remaining six months. A list of approved laboratories is sent to all county clerks in the state; supplementary lists are sent whenever necessary.

One of the greatest deterrents to reciprocity has been the lack of a standard premarital certificate form that could be used by all states. My own state, Oregon, is probably the worst offender in the number and variety of forms necessary to be filled out by the physician and laboratory. They vary in size, shape, and content. If a standard premarital certificate could be evolved from the conglomeration of forms used by the various states, a long step forward would have been taken toward interstate reciprocity. The Subcommittee of the Committee on Evaluation and Approval of Laboratories recommended in 1946 that the Conference of State and Provincial Public Health Laboratory Directors approve a standard premarital certificate form. It is my hope that this Conference will continue to give this matter its serious study. Unquestionably legislative action would be required in some states before a standard certificate could be adopted. Uniformity has been attained in birth and death certificate forms; it can be attained in the marriage certificate form also.

Personally I have been a firm believer in a national marriage law. Eventually I think we will have one. But until that time comes we can at least adopt a standard procedure for the laboratory portion of the premarital requirements. A serologic test for syphilis, accurately performed, will usually give the same results in Oregon as in Maine, in Florida as in Michigan. That has been demonstrated by the evaluation studies of state laboratories conducted by the U. S. Public Health Service for the past ten years. The errors inherent in the various procedures are being gradually eliminated by refinement of technique.

* States accepting out-of-state approved laboratory reports: California, Colorado, Florida, Kansas, Louisiana, Missouri, North Carolina, Ohio, Rhode Island, Wisconsin, Wyoming. Nebraska would accept reports conditionally.

The use of cardiolipin antigen, now being checked on a nation-wide scale, may offer another step in the improvement of syphilis serology. Availability of better trained technicians will shortly be an assured fact. Performance of serologic tests for syphilis by numerous hospital and private laboratories has been shown by intrastate evaluation to be on a par with control state health department or author laboratories. For all these reasons, therefore, reports from laboratories approved by their own state health departments should be given the same recognition and status as those from the state laboratories themselves.

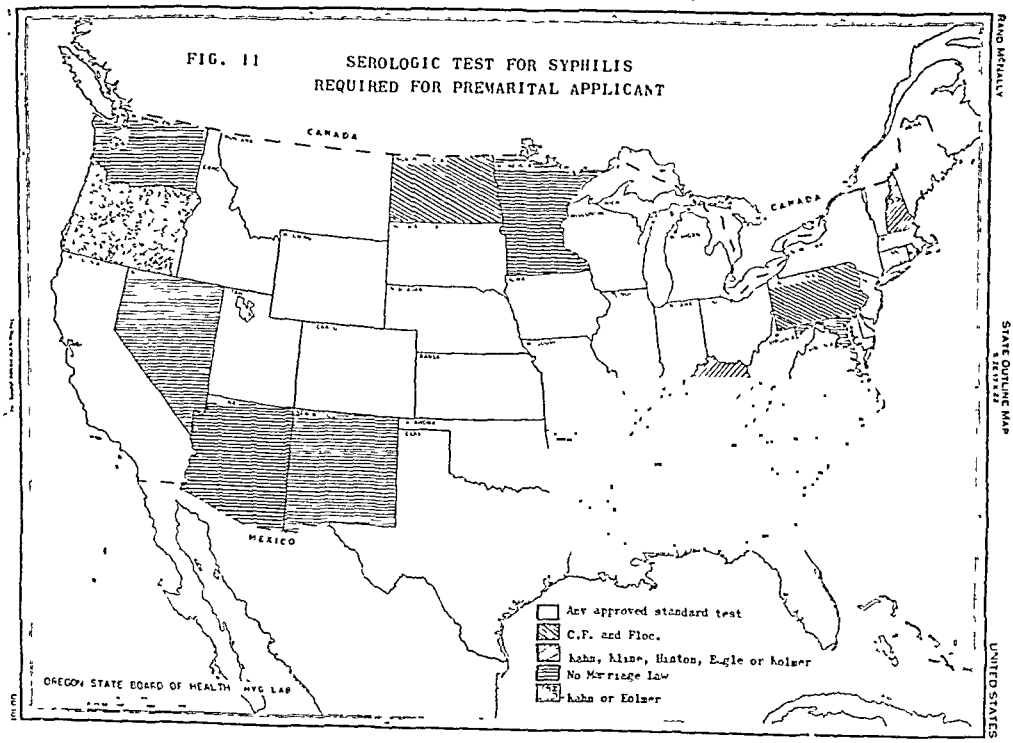
At the present time we have 52 laboratories in Oregon approved for the performance of premarital and prenatal serology tests for syphilis. These cover the entire state. Thirty of these laboratories made a total of 14,118 premarital tests in 1947. They thus contributed to the convenience of the persons concerned and to the enforcement of the state premarital law. We have found that many Oregonians go across to our neighboring state of Washington which has no premarital law, to escape the inconvenience of getting married in Oregon. Providing local laboratory facilities, therefore, is good business from all angles.

One objection to interstate reciprocity for approved laboratories which has been emphasized, but which is not insurmountable, is the reluctance or even the refusal of county clerks to accept out-of-state reports. It would seem that unless a state law specifically left this matter to the discretion of the license issuing authority, a refusal to accept an out-of-state report, certified as to its validity by the state department of health of the state in which the ceremony is to take place. would be null and void. The real problem of interstate reciprocity would be to arrive at some workable procedure to keep license issuing authorities informed of the names and addresses of all approved laboratories.

According to the subcommittee report already referred to, there were, in 1946, 2,184 approved laboratories in 27 states. The number of approved laboratories in any one state varied from 4 to 445. Unquestionably the number of approved laboratories will increase from year to year. In addition, a number of laboratories fail annually in evaluation tests and some approved laboratories go out of existence. Thus, two hundred laboratories changed status during 1946. It would require therefore, the full time of several clerks to tabulate information on approved laboratories and make out annual lists for distribution to all states.

The agency best suited as a national clearing house for approved laboratories is the U. S. Public Health Service. It already has the machinery for evaluation of laboratories in case evaluation by a central laboratory is desirable and feasible. It is scientific, disinterested, and has the confidence of all the states.

A standard laboratory form to be used by all approved laboratories can be devised which would give all the information required by the various states. The following information is suggested:



1 Date specimen collected
2. Date test made
3. Name, address, age, color, and sex of applicant
4 Name and address of physician
5. Results of serologic test or tests, giving name of test or tests made
6. Signature of director of laboratory
7. Certificate number or approval stamp indicative of its status as an approved laboratory

Several states issue rubber stamps which are used by their approved laboratories in identifying the reports as emanating from officially accepted laboratories. Alabama has issued a seal to its public health laboratories to be used for stamping certificates, and is contemplating the extension of its use to approved hospital and private labora-

tories. Other states, including our own, issue a certificate number to each laboratory; this number is indicated on the report. The use of a seal such as that devised by Alabama could be modified to meet the needs of each approved laboratory in any state by substituting the name of the state for Alabama, and inserting the certificate number given to each laboratory in the center of the seal. Each state could authorize the use of such seal by proper regulation, either loaning it to approved laboratories and maintaining ownership of it at all times, or else authorizing its purchase by the laboratory concerned. Each state would be responsible for the proper use of its seal. A standard laboratory report with the imprint of the seal could then be accepted nationally.

Figure II shows the kind of serologic test required by the various states.

The majority of states have wisely agreed that any standard serologic test for syphilis may be used on premarital blood specimens. Based upon use in the annual evaluation of syphilis serology tests conducted by the U.S. Public Health Service, the following may be accepted as standard tests: Eagle, Hinton, Kahn, Kline, Kolmer, Mazzini. A few states have their own modification of either the complement-fixation or flocculation test. Such modified tests could be made acceptable if their results in specificity and sensitivity fell within the required percentages for two annual evaluation series. North Dakota and Pennsylvania require both a complement-fixation and a flocculation test. The use of these two techniques in testing for evidence of syphilis was recommended by the Subcommittee of the Committee on Evaluation and Approval of Laboratories. Ohio requires a recheck if the first test is doubtful or positive. Many states make such rechecks a matter of routine. Oklahoma requires all positive and doubtful specimens to be checked by two different tests. Vermont permits any standard test; however, if the flocculation test is positive, a complement-fixation test must then be made. Laboratory examination, usually a smear, for absence of

gonorrhea is required in Illinois, and if indicated, in Kentucky, Louisiana (male only), and Oregon.

Space does not permit, nor does this paper warrant discussion of the relative merits of the various serologic tests for syphilis, or of the more controversial comparison of the flocculation and complement-fixation tests. Anyone interested can study the results of the annual evaluation tests or search elsewhere in the literature for comparative values. Suffice it to say, most states seemingly agree that any single standard test for syphilis, properly performed, is acceptable.

Another question which has given rise to some discussion is the number of specimens a laboratory should examine in the evaluation of its competence. Here a wide variety of practices may be noted. Some states require as few as 5 specimens, others as high as 200. Some states submit whole blood, others only serum specimens. In Oregon we send out annually 50 whole blood specimens, roughly 35 from syphilitic and 15 from normal donors. Sufficient blood is withdrawn from each donor so that every laboratory receives at least 5 ml. The subcommittee recommendation was to submit "not less than 75 blood specimens from presumed non-syphilitics and 75 blood specimens from syphilitics—the percentage sensitivity and specificity attained shall not be less than that required by the U.S.P.H.S. of state laboratories. . . ."

Frequency of inspection varies in the states from quarterly, semi-annually, and annually to every 3 years. In Oregon, inspection is made annually with a return visit if indicated.

SUMMARY AND CONCLUSIONS

Thirty-six states now have a premarital law requiring a physical examination and blood test for syphilis on both applicants; two states require a blood test, if necessary, on the male only. Laboratory reports from any state laboratory are accepted by all states. Any standard serological test for syphilis may be performed. Some states require reports to be made on their own forms; some will accept forms of other states. There is little uniformity in the forms of the various states.

Eleven states accept laboratory reports from out-of-state laboratories which have been approved by their own state department of health. More states would accept such reports if evaluation requirements were equivalent to their own. A standard syphilis serology report form for marriage applicants is highly desirable and would make the goal of interstate reciprocity easier of attainment. A seal to be issued to approved laboratories by their state department of health, which could, by substitution of the state name, be used in any state, is recommended.

Interstate reciprocity of premarital serological tests is particularly desirable among states which border upon each other's boundaries. California and Oregon already have such reciprocity. Washington, although not having a premarital law, does have a prenatal law which requires the performance of serologic tests for syphilis. Approval of laboratories by the Washington State Department of Health will be completed shortly and if their standards approximate those of Oregon, a reciprocal agreement will be entered into. Since, in the vast majority of states, the state department or state board of health is the agency responsible for the approval of laboratories, it would seem desirable that the Association of State and Territorial Health Officers initiate a study leading to the adoption of interstate reciprocity. The Conference of State and Provincial Public Health Laboratory Directors and the U. S. Public Health Service could be called upon to offer suggestions and recommendations.

I am not in agreement with a state laboratory director who replied to my

questionnaire: "Since the war is over I see no particular indication for expediting marriages." Love, like disease, knows no boundaries, and unlike disease we should not and cannot restrict it to the confines of any one state. The convenience of the public should always be considered. Forster and Shaughnessy hit the nail on the head when they stated: "Any public health measure should accomplish its objective with the least possible infringement on the normal activities of the citizens. Few of the prenuptial laws can be said to conform fully with this principle as far as interstate marriages are concerned." The attainment of interstate reciprocity in syphilis serology depends upon the interest and desire of those responsible for the administration of the premarital laws to carry it into effect. It can be done. It should be done.

WHO Alexandria Regional Office

Early in February representatives of 200,000,000 people in some 20 countries met in Cairo to set up the WHO Regional Office for the Eastern Mediterranean. It was decided to open this regional office in Alexandria on the site of the Sanitary Bureau on July 1, 1949. Sir Aly T. Shousha, Pasha, Egypt's Undersecretary for Health and Chairman of WHO's Executive Board was unanimously elected Director. For the first six months' operation, $100,000 has been made available by WHO.

Among the chief public problems awaiting action in the Eastern Mediterranean are schistosomiasis which is said to affect 65 per cent of Egypt's and 80 per cent of Iraq's population; hookworm disease, and malaria. The last named, through undermining the energy of the worker, is one of the principal causes of low food production in potentially rich agricultural areas. Others are the 3 T's—tuberculosis, trachoma, and typhoid.

Certain preliminary work of this regional office began in March—advisory services to Pakistan for malaria control, to Pakistan and Egypt in tuberculosis and maternal and child health, to Egypt and Turkey for venereal diseases, and to Ethiopia for training programs in such basic fields as public health nursing and sanitation. Also more than 30 study fellowships have been granted to medical personnel from this area.

Use of the University in Increasing the Expertness of the Nurse*

MARGARET S. TAYLOR, R.N., F.A.P.H.A.

Director, Course in Public Health Nursing, University of Minnesota School of Public Health, Minneapolis, Minn.

THE modern university is in a cogent and strategic position to offer leadership in the preparation of the professional worker for all fields of human endeavor. One of these very essential workers is the public health nurse.

The extensive facilities and personnel at the disposal of the university places a definite responsibility on it to assist in the preparation of the public health nurse, who must be especially well grounded, in the biological and social sciences and their application, to attempt to meet adequately the health problems and situations of today and tomorrow!

The very favorable position of the university for this purpose is enhanced when facilities are available within its campus for nursing education and public health as well as public health nursing education. However, whether this is a fact or not, it is imperative that the public health nursing faculty be deeply concerned with, and when feasible participate in, nursing education and curriculum construction and teaching on both the undergraduate and graduate level. This is a vital necessity if intelligent plans are to be formulated for advanced preparation of public health nurses.

The public health nursing curriculum has substance, only when it is built on a thorough knowledge of the content of basic nursing education as well as on the present and anticipated needs in the health field.

What then, are some of the vital present needs? One of the key positions today in schools of nursing is that of the faculty member responsible for integration of the social and health concepts of nursing. To date, too few universities have offered special preparation for this important work. Nevertheless, in many instances, with far greater enthusiasm than wisdom, public health workers have convinced schools of nursing of the necessity of having such personnel on the teaching staff. Too often, fine enthusiastic public health nurses are employed who are almost totally, if not entirely, unprepared for this type of arduous and exacting work. The inevitable result is confusion if not outright failure in the important program of integration of the social and health aspects of nursing throughout the basic curriculum. Added to this, is the disillusionment of all the personnel, the public health nurse, the general nursing faculty and the hospital personnel, as to the desirability of having a faculty and a curriculum which includes the incorporation of the social and health aspects of nursing. There are, of course, notable exceptions.

The National Organization for Public Health Nursing stands ready to give suggestions as to the recommended

* Presented before the Public Health Nursing Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

qualifications for the person taking such a position. Consultant nursing assistance when needed is available through the above agency, the regional offices of the U. S. Public Health Service, and the nursing divisions of state health departments upon request. It should prove very helpful to schools of nursing seeking this type of personnel to have these services. Effort should be made to have them fully utilized. When it is known what the preparation needs to be, there is a more reasonable chance for the employment of a qualified person and for the success of the undertaking.

It follows certainly, that the university must provide assistance in the preparation of this type of personnel through both theory and practice. To do so takes imagination and experimentation. However, at least two types of assistance would appear feasible, a long-range program of study that will prepare the mature and experienced public health nurse in this specialty, and a short-range study plan to bring together those persons now attempting this work to offer opportunity to thrash out problems together, exchange ideas, and gain new insight, thereby materially implementing knowledge and it is hoped ability, to do the job better. Simultaneously, there would be provided invaluable data from actual experience that could be sifted, then incorporated into the curriculum of the longer program of study. The latter would be for the nurse who showed particular potentialities and interest in this area.

Exceedingly important also is the provision for continuous, meticulous exploration and evaluation of the preparation in public health nursing, including both theoretical and field preparation given by the university to the potential public health nurse, or the public health nurse with limited public health experience. Moreover, efforts need to be directed toward determining the extent to which this preparation has succeeded and to finding its shortcomings. In part, this educational endeavor may be measured by the degree of ability actually demonstrated on the job by the recently trained public health nurse, and by determining how extensively and intelligently an assigned job is handled. Of necessity, then, a continuous critical and searching analysis must be an integral part of curriculum planning. This is tremendously important if the education given by a university for this group is to be alive, meaningful, and constantly geared to current and anticipated needs in the public health field. The analysis should be a joint one; the university public health faculty, the faculty in other departments of the university participating in the program, the service agency leaders in the community, together with the recipient of public health nursing preparation, the staff nurse, must sit down at specific intervals and assay and equate the assets and liabilities of preparation as offered. This is equally essential whether the preparation is given as a part of the basic school of nursing program, as in some collegiate schools, or as a program of study after the completion of basic school of nursing education.

Such a group analysis should offer an excellent opportunity to bring into sharp focus those parts of the program needing further study and to suggest possible modification and strengthening. By this means, preparation not only is more meaningful, but also is more apt to be kept dynamic.

A full-time faculty member who acts as a field coördinator is of great assistance in this regard, especially when field placements encompass a large geographical area.

Routine field placements as such may then to a large extent be obviated, and more attention given to individual background, needs, interests, and personality. After thoughtful examination, all these factors may be carefully considered in

relation to the particular type of program and the general philosophy of the agencies used. The so-called routine first-level field experience then, not only correlates more nearly with theory, but becomes a far more vital and stimulating experience for both the student and the agency. The university can and should do much to prepare the student to take a major responsibility for implementing the depth and breadth of the field experience by her own thoughtfull approach and frank discussion of the experience. Much of value may result from a sincere attempt to evaluate performance as a professional worker, with full cognizance of the limitation imposed upon the situation by both lack of or limited previous experience of the learner and also by the type of learning opportunity at hand. The student's ability to accept and to use effectively this opportunity for self-direction in field experience will depend to a considerable degree upon the responsibility previously given the student in the university, under guidance, to build a program of study which permits discriminating but broad choice of electives in public health and related fields. The required courses or core curriculum should be limited to the irreducible minimum. Actually there is need for relatively few fundamental courses. This is not the hazardous assumption it might appear at first, but rather a sound one lending itself to materially strengthening on an intelligent, selective basis, individual program planning. It places primary responsibility for planning on the person most concerned, the learner, thus affording a rich opportunity to the prospective public health nurse, that it is hoped will encourage continuous self-education and self-analysis.

The above discussion presupposes that the agency and its field teachers are ready and willing for provocative questioning by the student. It is the university's definite responsibility to stimulate the field agencies' interest in this type of broad field experience by interpreting its creative aspects, and the anticipated greater expertness that should develop on the part of the learner. For through increased participation, assumption of more responsibility and greater self-stimulation, the prospective public health nurse, it is reasonable to expect, will be definitely assisted, in gaining expertness in the practice of public health nursing and in growth as a professional person that will make for distinctly increased effectiveness.

Another method that might be used in addition to the field conferences, by and with the field coördinator, to increase nurse expertness, would be to have workshops for field teachers. If such continuation study is deemed desirable, consideration should be given to two types of workshops — the "pseudo" workshop for the about-to-be field teacher, or those with very limited experience in this activity, and the "true" workshop where field teachers will bring their actual problems for study and discussion. In both instances, the assistance of many different experts from various fields such as business administration, education, and the like, usually will be readily available in the university for the asking, granted. that at times they must be smoked out. Such persons bring an invaluable fresh approach and materially aid, not only in enriching a period of intensive study, but they also lend definite assistance to the solving, on a broad basis, of some of the knotty problems presented.

One precaution appears warranted. To be assiduously avoided, is the tendency on the part of universities to repeat special intensive work on the same level, time and again. For example. what is invaluable on an elementary basis to the beginning field teacher, has little of value or stimula-

tion for the field teacher of several years experience. Greater expertness is needed by the workers in each group. Therefore, continuous critical analysis of such programs offered is vitally essential. Otherwise, sincere attempts on the part of the university to increase nursing expertness will be, at one point very meaningful, at another superfical and dull, defeating the immediate purpose and stifling future interest.

Through their own resources and by the importation of special consultant assistance, all universities are probably able to meet on a short-term basis in a reasonably satisfactory way practically any need in a specific area, and they should; however, there is also the crying necessity for universities to be ready to offer special preparation in specific areas on a long-term basis, through developing complete programs of study with correlated theory and practice.

Not all universities will be able to give rich opportunities in each of the areas of specialization equally well. Therefore, serious cognizance should be taken of this fact and each university should scrutinize its resources to determine those areas of specialization in public health where it feels it has unusually rich ones, either developed or that could be developed for advanced study, whether this study be in supervision, mental hygiene, administration, or some other phase of public health nursing work. Then the task should be to concentrate on development in this area or these areas. Such information should be given wide publicity and, of course, should be known to all universities concerned with the education of nurses so that students may be directed where they will receive the finest and most complete preparation possible. Another important reason for detailed information about such programs being readily available, is so that another university will not be starting a similar program when the need is being well and adequately met, but rather direct its energy to assay unmet needs in the health field. It is assumed that a thoughtful detailed study by the university, of course, will precede the establishment of any program, to determine if resources are rich and extensive enough either to be supplemented or developed for the special program of study needed by advanced public health nursing students. As this is done more widely, beginning and advanced preparation will be strengthened. To develop areas of special preparation adequately would seem to necessitate not only the planning mentioned above, but also the initiation of more extensive plans for internships. There is nothing new about this suggestion of internships. They have been urged by outstanding public health leaders for years, but in too few places are internships actually available so that theory and potential expertness may be put into operation under guidance over a sufficiently long period of time to enable some degree of significant practical expertness to mature. Long-term planned field practice is an essential ingredient of any advanced program of study in public health. Actually it is the very foundation on which final expertness rests, granting that always more knowledge and experience are needed to gain stature as an expert. Little can be developed of intrinsic worth without a strong foundation that has been painstakingly built.

Assistance from the university to the field agencies and vice versa in strengthening the preparation of public health nurses for various types of positions, such as that for the beginning worker and for the seasoned public health nurse interested in increasing general competence in the field of public health, or in some special aspect of it, should be continuous. For such preparation will be ever changing. Meanwhile, the

alert university will keep its finger on the pulse of community needs, as well as have the vision to see beyond, to national and international health needs and constantly envision and formulate concrete ways in which they may be met and then put these ideas into action as an integral part of the curriculum.

Furthermore, the university may well be utilized to assist with agency inservice education. There are various methods by which this may be accomplished, only two of which will be mentioned. One, university personnel may act on a consultant basis and assist thereby with the development, launching, and evaluation of inservice educational programs. Such a plan implies use in a limited geographical area to make it feasible. For example, the supervisors in a local agency might be concerned with the development and use of proficiency, efficiency, and evaluation reports, and might quite well turn to the university personnel for assistance over a period of time, perhaps a year, in studying ways and means of handling this very essential and delicate function of every public health nursing supervisor.

Another method might be to have university personnel actually give, individually or as a member of a team, special assistance in an institute or workshop type of conference for a group of public health nurses or a group of community workers. Included might be nurses from all nursing fields. Here the techniques of group dynamics might be utilized advantageously to stimulate discussion and to demonstrate an effective method of teaching. The specific content given could be planned to meet particular current public health problems. For example, the matter might be handled by a workshop centered around such a problem situation as, the use of the mental hygiene approach in the understanding and the handling of chronic illness by public health workers, nurses, doctors, and social workers. This type of conference would be concentrated over a short period of time. To plan and complete means for follow-up and evaluation of results *before* undertaking the project would be imperative. This is an exacting and tough task.

Too frequently in the past, and even today, a stereotyped pattern has been followed in organizing an institute or group conferences. They have entailed the giving of mammoth quantities of didactic material with little or no regard for group participation, or for scrutinizing results after a period of time by criteria determined before the conferences began. Granted, this latter may be difficult; the results disconcerting! Certainly if the assets do not outweigh the liabilities, they should be known and faced and the method discarded or revamped and revitalized.

It is readily seen that this discussion might go on for some time. Actually the extent of the university's usefulness in increasing nursing expertness is indeed limitless. In summary it might be said, provided personnel and facilities are available—and they are, within most universities—what is needed urgently is leadership, initiative, resourcefulness, and creative imagination to use what is there. Unfortunately this lack is, often, the only deterrent. Since they may prove provocative to others, mention will be made of those areas in which one university has found public health nurses constantly and repeatedly requesting assistance to increase their expertness. Of course, it is not too hazardous to guess that these requests are far from unique, but rather of the very common garden variety. They fall under the following general headings:

1. General overall program planning
2. Budget making and cost analysis
3. Coördination of functions of various health and welfare groups and the determina-

tion of the limits of responsibility of each
4. Effective use of community councils
5. Planning of special educational programs to increase scientific knowledge and to facilitate its use

An essential corellary to the foregoing comments might well be that the public health nursing faculty, to give leadership and guidance as indicated, must be well prepared for the job by actual academic preparation and wide and varied public health experience, and that each faculty member must constantly be broadening and deepening individual perspective while simultaneously gaining greater specific knowledge and adeptness in application. Therefore, there is a crying need for greater opportunity than may be gained in such a meeting as this for a university nursing faculty to sit down together, thoughtfully pooling and exchanging ideas and methods. Such work conferences would facilitate and stimulate continuous growth of the faculty which must be ever alert to ways of maintaining and improving nursing expertness. Moreover, it should be remembered that to develop nursing expertness there is unanimity of opinion that there must be opportunity to gain theoretical knowledge and opportunity for practice in its application. Both should be well coördinated and integrated.

To date, the opportunities for university faculty to be exchanged with agency personnel have been sporadic. Is this not something that should be explored, developed, and put into operation on a wider scale without delay? Then, the university as well as being in a strategic position to offer leadership, would actually tend to maintain a high degree of competence in operation. Then, the university would become a dynamic center of learning for health workers with the field agency as the laboratory—the testing ground. Functioning in this manner, the university could not but contribute markedly and continuously to increasing the expertness of the nurse.

Leslie Dana Medal to Dr. Post

The Leslie Dana Gold Medal for 1948, a national award given annually by the St. Louis Society for the Blind for outstanding achievement in the prevention of blindness and the conservation of vision was presented on March 25 to Lawrence T. Post, M.D., of St. Louis.

This award in the field of public health is given upon the recommendation of the Association for Research in Ophthalmology.

Dr. Post is Professor of Clinical Ophthalmology and head of the Department of Ophthalmology at Washington University Medical School. He is Ophthalmologist-in-Chief at Barnes Hospital, McMillan Hospital, St. Louis Children's Hospital, and the Washington University clinics.

A School Health Demonstration Based on Sound Public Health Practices*

THOMAS R. HOOD, M.D.

Formerly Director, Kansas School Health Demonstration, now attending School of Public Health, Harvard University, Boston, Mass.

A PRESUMPTIVE title was chosen for this paper without conceit but with the firm conviction that much of the Kansas School Health Demonstration is basically sound, and that the policies involved are important in the development of a program which is practical and includes a majority of the factors affecting the health of school children.

A State Health Education Council was formed and numerous working committees were appointed in 1944.[1] The council studied school and community health problems and made specific recommendations for promoting and building stronger local school health programs. They observed that the health of the school child is affected by many events which occur outside of the school walls. They believed that a program directed only at children in school is narrow and not so likely to produce real results as a community health program. Their conclusion was that the best program was a community-wide generalized public health program with moderate emphasis on services to the child from the time of its conception until it is through school.

Certain excellent manuals[2] were compiled and edited by the State Health Education Council and published by the State Board of Health and the State Superintendent of Public Instruction.

Having developed concepts and manuals, the council wished to reduce the ideas to practice in the form of a 5 year school health demonstration. Cowley County, Kansas, was selected as one of the favorable places to conduct such a demonstration[3] and state and federal funds were made available to supplement local funds in carrying out the program.

Cowley County is essentially a rural county of 35,000 population, containing two towns: Arkansas City 13,000, and Winfield, 9,000. There are two junior colleges and one university in the county.

A budget of $35,000–$40,000 has been used and the staff was originally planned to include a health officer, a pediatrician (loaned from the State Health Department), a supervisory nurse, 8 public health nurses, a sanitary engineer, a sanitarian, 2 clerks, and a statistical clerk. At no time have all positions been filled. If we were embarking on this venture anew, we would certainly include a full-time health educator.

In this county of 35,000 population, prior to reorganization, 7 separate agencies employed 11 public health workers. The agencies included the county, each of two towns, two school boards and two public health nursing associations.

When this demonstration was proposed, we met with interested individuals and groups to discuss the proposal and to seek their active coöperation in car-

* Presented at a joint session of the American School Health Association and the Public Health Nursing, Public Health Education, Maternal and Child Health, and School Health Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

rying out a health program of the general type suggested.

This local organizational work was done rather rapidly and was completed in about 2 months. Various questions about such reorganization were raised by individuals and groups: that it was "socialized medicine"; that state and federal agencies would run it; that certain specialized jobs (bedside nursing) might not be done as well by the new organization; that personnel presently employed might not meet merit system requirements.

The argument relative to socialized medicine was met by three facts: the local medical society approved of the reorganization and its more extensive public health services; the Health Department efforts do not include treatment of diseases or defects, therefore, do not constitute practice of medicine by a governmental agency; the additional and more adequate health services to the people of the community would make them more, rather than less, satisfied with the total health service available to them, hence would tend to reduce demands for the socialization of medicine.

The question of outside control and the misgiving that specialized jobs might be neglected were answered by pointing to the local board of health which had the responsibility of developing the program in a way to meet the needs and demands of the community. Although we hoped that all groups would stay in for the whole 5 year period, an "escape clause" was included in the resolution so that one or more groups might withdraw on 6 months' notice. To date, no group has utilized this clause.

Existing personnel did not all meet merit system requirements. One individual took a special examination to qualify. Others became permanent employees after revision of a clause of the merit system to accept them as incumbents. If reorganization had included the necessity of discharging public employees of long service and considerable following, the reorganization would have been impossible.

By resolution, the 7 agencies combined their finances, personnel, and interests in the "Joint Health Department of Arkansas City, Winfield and Cowley County." The resolution established a Board of Health with a representative from each of the agencies involved and from the medical and dental societies.

As soon as reorganization became effective, extensive reorientation of the staff began. Nurses who had previously done only bedside services, school nursing, or inadequate county-wide services were brought into the Health Department and given the task of doing a generalized program within an assigned district. The duties of the Health Officer and the sanitarian expanded suddenly and explosively.

Continuing efforts have been made to inform the community of the aims, objectives, and work of the Health Department through newspapers, radio, community meetings, talks to civic clubs, observance of Public Health Nursing Week, and through the Board of Health and the daily contacts of the Health Department staff. A special effort consisted of a Health Education Workshop held in conjunction with the rural teachers' institute. A second workshop this fall included teachers from the two towns with the rural teachers and many community leaders. These efforts have materially increased the understanding of the community and of special groups. Needless to say, such efforts must be perpetuated and expanded.

We will now proceed to discuss the pattern that our generalized services have developed and needed alterations therein. Services have been designed to foster and encourage individual responsibility for health and to supplement and aid the practising physician rather than supplant him. Health Department serv-

ices are available to all people of the county, not merely to the indigent. We believe that the program gathers much strength and support from following these policies.

Expectant mothers and unborn children have had nursing service, but no prenatal clinics have been held. Good prenatal care is rendered by private physicians; provision is made for care of indigents and our objective is to get patients into the practising physicians' offices rather than into a prenatal clinic. Our prenatal services have been at low level but have gradually increased in amount. Mothers' classes are being started to serve this group.

A premature center is being developed in one of the local hospitals and our nurses are aiding a gradually increasing number of mothers and new-borns when they return home from the hospital. Home deliveries are rare but a nurse assists with them before, during, and after delivery.

At several centers in the county we have regular well child conferences for infants and preschool children. Through these conferences families are encouraged to seek regular health supervision from their family physician. Any infant or preschool child is eligible for these conferences if he is not already receiving medical supervision of a physician. In isolated areas, screened school children are examined in these conferences.

Health supervision of school children includes, if possible, a final preschool examination at the well child conference or by the family physician, or, if not possible, an examination soon after entrance. From then on examinations are done after screening by teacher and nurse. A summary of each child's preschool record is placed on his school record when he enters school. Children known to be entering school in the fall are sent a letter explaining the need for a health inventory including a dental examination. Blank record forms are enclosed. The suggestion is made that they get this service from the family physician, but the door is left open for their parents to make an appointment for conference at the Health Department.

When screening is done on children in school, such an option is offered again. A large proportion of these children go directly to the family physician. The nurse informs the family physician of the reasons for referral. Does this procedure have any advantages? We think so. It is highly acceptable to the local physicians; it requires less nurse and health officer time because there are fewer children and parents to be served at our conferences; the need for nurse follow-up is greatly reduced; less effort by parents is needed because only one visit is made in lieu of two; direct remedial action can be taken at this visit; it encourages individual responsibility. The defect of the plan lies in the difficulty of getting pertinent data from the physician for the school health record. This is solved in part by returned referral slips with notations on them. Direct referral of selected children to the family physician promises to be one of our most successful procedures.

Other services have evolved into a certain pattern. Immunizations are offered at conferences—every other year in the larger schools, in any elementary school where the immunization level for smallpox, diphtheria, or whooping cough has fallen below 75 per cent. Last year a truetone audiometer test and the Massachusetts vision test were done on all school children in the county, grades 1 through 12. In the coming school years we expect to use these devices to test grades 1, 3, 6, and 9, plus all new students and those screened as needing a test. Snellen test and observation are to be relied upon for children in other grades. The Snellen test will, we believe, find children who develop myopia rapidly; the more complicated vision test includes means to detect pathological

conditions which develop less rapidly, and hence may logically be done less frequently.

Dental inspection has customarily been done annually on all school children in the two major cities. Last year it was done for the first time on rural school children. Such inspection, while it has been of considerable value, violates the principle of encouraging individual responsibility for dental care, and, in fact, does not even teach children to visit their dentist once a year. It does teach them to wait for the inspection provided to find out whether they need to go to the dentist. We are seeking to alter this automatic inspection to a program designed to educate parents and children to seek annual dental inspection and care from their own dentist.

Sanitation work has been productive in several ways. Rural school sanitation has been improved under the guidance of the public health engineer. Milk sanitation has been much improved by generation of public support for proper sanitation and by adoption and enforcement for the first time of Standard Grade A Milk Ordinances in the two principal towns. City-wide DDT spraying was introduced in the two towns and is being incorporated with the city governments' other regular services to the public.

Teaching of health to children has been done in the schools, and the state and local school people have developed unit material toward this end. Teachers have integrated health teaching with other subjects and our staff correlates it with their services.

The remaining basic health services were organized and conducted in a fairly routine fashion. We must mention one undertaking which we regard as a major error in policy and planning.

We devised and utilized a mass technic in our overzealous efforts to render services efficiently to children in scattered and small rural schools. Centers were used and children from nearby schools were transported to one of them at a scheduled time. Once there, each child had, in rapid succession, a vision test, hearing test, dental inspection, and immunization. On certain days they also had a brief physical examination by a physician. Nurses and teachers were present but no parents. Follow-up reports were filled out later and mailed to the parents.

This method had two merits—it gave the examining physician an interesting cross-sectional view of the physical status of school children and it mechanically provided some services. Its shortcomings are almost too numerous to mention, but include: no opportunity to confer with parents and to observe familial characteristics in them; excessive disruption of other work; lag in nurse follow-up; bizarre reports carried home by the children; complete lack of real educational value. The public relations feature was poor in that services carried to each rural school do much to engender knowledge and support of the health department and its activities.

Services to preschool children have been satisfactorily active. Those rendered to elementary school children have been disproportionately numerous. As community understanding and planning progress, services should increasingly be directed toward the prenatal and neonatal groups. In addition, more services should be available in secondary schools and colleges.

SUMMARY

The Kansas School Health Demonstration was started after state-wide organization and planning and after reorganization of local services. It is based on the idea that the health of the school child can best be improved through a generalized well rounded public health program which places moderate emphasis on the health of the child from con-

ception onward, rather than one which confines itself to activities within the school. Increasingly, it has stressed the importance of individual responsibility in obtaining suitable health guidance, and has sought to educate the individual to recognize the importance of his health and stimulate him to seek it for himself and his family rather than to wait for government or charity to provide for his needs. Services are available to all, regardless of financial status. The program has been directed toward supplementing rather than supplanting the work of the practising physician and dentist. It is an attempt to demonstrate that a health department of reasonable size can, coöperatively with school systems and other local groups, develop and carry on the type of program described in a unified, effective manner.

Cardiovascular Disease Control Committee

The National Advisory Heart Council of the National Institutes of Health has selected a subcommittee to assist in passing upon requests for grants to finance community control projects. Although no appropriations have yet been made by Congress (March, 1949), applications for research and construction grants aggregating many millions of dollars have been received by the Council.

The members of the subcommittee are:

F. C. Beelman, M.D., Director, Kansas Board of Health
Marjorie Bellows, Statistician, American Heart Association
William H. Bunn, M.D., Practising physician, Youngstown, Ohio
Charles A. R. Connor, M.D., Medical Director, American Heart Association
C. Mayhew Derryberry, Chief, Health Education and Training, U. S. Public Health Service
T. Duckett Jones, M.D., member of the Council and Medical Director, Helen Hay Whitney Foundation, Chairman
Ruth E. Lynch, Los Angeles County Tuberculosis and Health Association
H. M. Marvin, M.D., President-Elect, American Heart Association
C. Martin Mills, M.D., Health Officer, Richmond, Calif.
Mary B. Moss, Executive Secretary, American Association of Medical Social Workers
David D. Rutstein, M.D., Harvard Medical School
Marion Sheehan, University of California School of Nursing
Estella Ford Warner, M.D., Chief, States Relations Division, U. S. Public Health Service

Laboratory Handling of Radioisotopes in Cancer Research*

SHIELDS WARREN, M.D.,[1] AND JOHN Z. BOWERS, M.D.[2]

Division of Biology and Medicine, U. S. Atomic Energy Commission, Washington, D. C.

IT is not facetious to say that the impact of the development of the atomic bomb has been felt as keenly as a contribution to the welfare of mankind, as in the programs for the development of weapons to destroy mankind. The chain-reacting uranium pile which can be used to manufacture plutonium, a basic component of an atomic bomb, can also be used for the manufacture of radioactive isotopes, which, as of June 30, 1948, were being used in 247 industrial and educational institutions for research and therapy. Actually, radioactive isotopes had been prepared for a number of the elements before the Atomic Energy Project. Through the use of high speed accelerators it was possible to bombard the atomic nuclei with particles traveling at a sufficiently high speed for them to penetrate the nucleus and render it radioactive. By this method several hundred radioisotopes had been prepared, but many only in microgram amounts. In the chain-reacting pile the enormous number of neutrons liberated by the fission of uranium penetrate the atomic nuclei and render the target atoms radioactive on the scale of milligrams, grams, and even kilograms of radioactive material.

You will recall that the atom consists of a nucleus which contains charged particles called protons and uncharged particles called neutrons. If a charged or an uncharged particle penetrates the nucleus it may disturb the normal balance between protons and neutrons so that the nucleus is in an unstable state. However, the nucleus tends to return to a stable state and to do so, it emits detectable particles or radiations until a normal balance between protons and neutrons once again obtains. By the use of a Geiger Muller counter or an ionization chamber it is possible to count the number of these radiations emitted and so not only determine the presence of a radioactive isotope but, in many instances, the amount of material. It is often possible to use very small amounts of material as a tracer. Thus, in a typical tracer experiment using radioactive iodine only some 4×10^{-14} grams of radioactive isotope are required.

As of this date, radioactive isotopes are finding wide applications in cancer research. An increasing number of compounds labelled with radioactive isotopes are available for research studies such as steroid hormones, carcinogenic agents, and amino acids. In using these radioactive materials a number of considerations should be borne in mind from the laboratory standpoint.

Laboratory precautions in handling radioisotopes differ with the type of radiation emitted. Beta particles are moderately damaging but are in general of short range and only superficially penetrating. Accordingly the hazard in handling isotopes emitting beta particles

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

1. Professor of Pathology, Harvard Medical School, Boston, Mass.

2. Assistant Professor of Preventive Medicine, Johns Hopkins University School of Medicine, Baltimore, Md.

lies more with a localized overexposure in contrast to gamma-emitting radioisotopes where the hazard lies with total body irradiation rather than with localized exposure. Thus, the hands of the experimenter using beta emitters are most likely to be overexposed and lucite holders, shields, and thick walled glass containers are usually adequate for shielding. However, the area should always be monitored by the experimenter, for the more energetic beta particles have a range on the order of a meter of air. Radioactive phosphorus which is receiving wide usage in the treatment of leukemia, polycythemia, and lymphoma is a pure beta particle emitter, with a maximum energy of 1.71 m.e.v. Radioactive carbon which has been used to tag methylcholanthrene and urethane is also a pure beta emitter with an energy of only 0.145 m.e.v. Such soft radiations, as with carbon, are readily absorbed by any solid material and adequate protection against millicurie amounts may be found by using a minimum of 6 inch distance from the source with heavy rubber gloves for the protection of the hands.

Gamma rays are quite similar to X-radiations; they are less damaging than beta particles per given amount of tissue exposed but the total amount exposed is much greater because of a high degree of penetration. The interposition of material, such as lead, or distance between the worker and the source is the best protection.

To complete the picture, mention should be made of alpha particles which are highly ionizing but are of such short range in tissue that they are usually unable to penetrate the heavy layer of the skin. They are not encountered in ordinary research experiments.

A number of radioisotopes that emit both beta particles and gamma rays are being used in cancer research. Radioactive iodine has been used in research on the location and treatment of thyroid cancers. This isotope emits beta particles and gamma rays and, accordingly, careful shielding is necessary. Radioactive sodium also emits both beta particles and a highly energetic gamma ray. It has been used in research on the treatment of leukemia.

The amount of radioactive material used is of course highly important. The microcurie amounts used in tracer experiments do not require the precautions for using materials at the millicurie level.

Our knowledge of the permissible safe dose of radiation that a human being may receive in one day is based largely on animal experiments. Previous permissible daily dose has been established as 0.1 roentgen per day but will probably be lowered. By the permissible safe dose we mean the maximum amount of X or gamma radiation to which a normal individual can be exposed in the unit of time specified without immediate or long-range harmful effects. Thus, 0.1 roentgen will *not* alter the hemogram, induce mutations, or impair gonadal function.

It is important to realize that the most important step in dealing with the overexposure problem is to detect potentially harmful amounts of radiation at the laboratory instrument level. The realization of the danger from a particular substance because of the detection by instruments of the intensity of its radioactivity is much more important than the ability to carry out a careful hemogram after exposure. There are two simple devices which may be used to determine the amount of radiation to which a person has been exposed in a particular experiment, and any person handling radioactive materials should wear one of these at all times in the laboratory. The simplest is a piece of dental film contained in a badge which is developed and compared with film exposed to known amounts of radiation. Second, pocket electroscopes are of value, espe-

cially for immediate knowledge as to the amount of radiation to which an individual has been exposed at any given time.

In expressing the time during which a radioisotope retains its radioactivity, the term half-life is used, meaning the time in which one-half of the radioactive atoms disintegrate. The fact that in some instances it means thousands of years emphasizes the care that must be used to avoid ingestion accidentally or of contamination of material. Thus, one of the presently used radioactive isotopes of sodium has a half-life of 3.0 years. Contamination of a table, a floor or similar permanent equipment by spilling this material may demand extensive and expensive replacements before the laboratory can be used safely. Radioactive carbon has a half-life of 5,100 years. Thus, although its very weak energy makes the external hazard minimal, if ingested it will produce radiation exposure for a lifetime. Accordingly, it is not presently used in cancer research in human beings.

In addition to the avoidance of ingestion of radioactive material, consideration must also be given to the introduction of radioactive isotope through a laceration, and the subsequent localization of the material. Thus, radioactive strontium which, because of its metabolic similarity to calcium, has been tested in the treatment of bone tumors, has been shown by Brues to cause osteogenic sarcomas in rats because of its tendency to localize in bone.

The problem of disposal of radioactive wastes has many questions that are still unsolved. In several instances the radioisotope has such a short half-life that it is a relatively simple matter to retain the material in a lead-lined container until a majority of the atoms have disintegrated.

Since it is known that plant and animal life can concentrate the various elements, a dilution of the material with non-radiative element is often advisable.

A consideration of the carcinogenic effects of radioisotopes naturally raises the question of the incidence of cancer in patients who have received radioisotopes as a therapeutic agent. In 217 cases of leukemia receiving radiophosphorus and 94 cases of polycythemia receiving the same material, Dr. John Lawrence's statistics do not show evidence of an increased incidence of neoplasm. This series includes cases treated over a 12 year period. We have had no other evidence of increased incidence of cancer in patients receiving radioisotopes.

The sensitivity of the hematopoetic tissues, especially the leukocytes, to radiation, has resulted in widespread use of the blood count as a continuing check on possible deleterious effects of radiation. It is suggested that persons exposed to radiation should have a monthly blood picture with particular attention to total white blood count and the lymphocyte level. Studies are in progress in the laboratories of the Atomic Energy Commission and in civilian institutions under AEC support on the use of radioactive cobalt as a radiation source similar to radium.

Radioisotopes are distributed from Oak Ridge, Tenn., by the isotope distribution branch under the able leadership of Dr. Paul Aebersold. Before these materials are allotted to institutions, a careful investigation is made of the facilities and protective measures available in the laboratories. Through the field service of the Radioisotopes Branch close liaison is maintained with those laboratories using these materials so that proper protective measures are constantly in force. The record of the Commission, as well as the record of the institutions participating, emphasizes the fact that through knowledge of the materials used and constant safety precautions it is possible to carry out extensive research without jeopardizing

the health of the personnel. At present the AEC is distributing without charge radioactive phosphorus, sodium, and iodine for cancer research. As other new isotopes become important in this field it is anticipated that they will also be distributed without charge.

There is at present no cancer cure in the field of radioisotopes and we know of no cancer case that has been cured by the use of these materials. However, radioactive phosphorus is felt to be the treatment of choice in polycythemia vera, while in chronic leukemia radiophosphorus gives, in general, the same results as radiation therapy with the distinct advantage of the absence of radiation sickness. It would appear that in radioisotopes we have a tool which may prove extremely valuable in studying the genesis and growth of cancer, and intensive studies are under way on the use of radioisotopes in cancer diagnosis and cancer therapy.

A.M.A. Section Plans Symposium on Smog

In view of the lively interest aroused by poisoning from smoke or smog in such situations as that at Donora, Pa., attention is directed to a symposium on air pollution, including smoke and smog, scheduled at the annual meeting of the American Medical Association, June 8, in Atlantic City, beginning at 9 A.M. under the auspices of the A.M.A. Section on Preventive and Industrial Medicine and Public Health. Rutherford T. Johnstone, M.D., Los Angeles, is the Secretary of the Section.

Dr. Johnstone points out that in spite of a good many air pollution studies the public attention has only recently been alive to this issue since the Donora episode. The lay press has contained sensational articles which have stirred up the general public to ask their physicians and their health officers about the nature of smoke and smog.

In the panel as planned the chemical topographical, and meteorological aspects of smog will be presented by H. F. Johnstone of Urbana, Ill.; recent advances in the identification of air pollutants by J. A. Haagen-Smit of Pasadena; causes, constituents and physical effects of smog involved in specific, dramatic episodes (Donora; Meuse River Valley) by H. H. Schrenk of Bethesda; general health aspects of industrial and community smog by William Ashe, Cincinnati; approved control measures by W. C. L. Hemeon, Pittsburgh; administration of an air pollution control program by L. C. McCabe of Los Angeles; and summary and discussion of papers by Robert A. Kehoe of Cincinnati.

A joint session on air pollution under the auspices of the Subcommittee on Air Sanitation of the Committee on Research and Standards, Alexander D. Langmuir, M.D., Chairman, will be held in connection with the 77th meeting of the American Public Health Association in New York City in October.

PHYSICIAN, HEAL THYSELF

MOST health officers today realize that a child guidance or mental hygiene clinic, staffed by psychiatric personnel, is an essential element in the public health machinery of any well organized community, alongside of its maternal and child hygiene, tuberculosis, and venereal disease clinics. Many of them understand that such a mental hygiene clinic is not—by itself—a complete answer to the problem of emotional health. The traditional health services deal with particular age groups or particular diseases and their programs are, in large measure, mutually exclusive. Not so with mental hygiene. This is perhaps the most nearly universal problem in the entire field of public health. It affects every age group, it complicates every disease condition. Therefore, the mental hygiene approach must permeate every activity of the soundly planned health department.

Our thinking along this line has been greatly stimulated by recent events in the State of California.[1] In 1945, when the State Health Department became responsible for setting up preventive mental health services, Dr. W. L. Halverson, State Health Officer, asked The Commonwealth Fund of New York for help in working out suitable plans. The Fund sent a physician with pediatric and psychiatric training to study the problem. He took the position that awareness of interpersonal relationships was the cornerstone of mental health, and on his advice the State Health Department employed, in 1946 (also with assistance from the Fund), a full-time mental health consultant who shared this belief. In his first year and a half this physician not only thrashed out basic issues with his colleagues on the state staff but demonstrated and taught the possibilities of a mental health approach to clients in local health service. In 1947, some of the men he had worked with were eager for more contact with psychiatric thinking. In response to their wish the Fund joined forces with the State Department of Health to organize an institute on mental health in public health which was held at Berkeley for the two weeks beginning July 5, 1948.[2]

The twenty-seven "students" and sixteen "teachers" who came together for this institute promptly began to talk about public health problems on an equal and informal footing. The students were all public health administrators, mostly

city and county health officers. Three of them, from outside California, represented the states where The Commonwealth Fund has been most active in support of public health: Tennessee, Mississippi, and Oklahoma. The teachers were a carefully mixed group—eight psychiatrists, three pediatricians with psychiatric training (chosen with the potentialities of the well child conference in mind), and five public health leaders to serve as interpreters and referees. There were observers from the U. S. Public Health Service, the U. S. Children's Bureau, and the Oregon State Health Department.

The plan of the institute included lectures, clinical work, and group discussion. The lectures revealed certain glimpses of psychiatric therapy—the developmental history of the personality, the nature of anxiety, the problems of authority—with some data on the epidemiology of mental diseases. The most important factor was the clinical work, conducted in the regular clinics of the health departments of Berkeley, Oakland, and Richmond where psychiatrists demonstrated, and many of the students themselves conducted, leisurely interviews with typical patients—mothers in the antepartum and well baby clinics, crippled children, tuberculosis suspects, syphilitics.

Finally, in group discussions, the whole educational process was brought to a focus. "The students and their leaders got together daily in small sections, occasionally in larger groups, and informally at evening 'bull sessions.' There was talk of alcoholism; the relations of the health officer with the newspapers; social medicine; budgetary problems in public health; what to say to the parents of a defective child; how to gauge the emotional maturity of a candidate for a job; staff parties; nursery schools; the fear of death and the question of immortality; whether psychiatrists tend to think of pleasing the patient; unmarried mothers and whether or not they should keep their children; the difficulties imposed on the health department by civil service; the case of a woman who married, against advice, a man who beat her and why women do such things; the boss as father symbol; how to train and supervise part-time physicians in the health department; what responsibility public health carries for altering cultural patterns; when an interview is therapeutic; the limitations of psychotherapy as applied to mass problems. None of the psychiatrists attempted to impose a preconceived program on the discussion, and the freedom with which men ventilated their professional and personal problems, their skepticism with respect to psychiatry, and their puzzled resentment against mental health propaganda was an indispensable part of the process by which group thinking became integrated."

The institute apparently achieved three major results. In the first place it made clear to a group of health administrators that psychiatry has much more to offer than the diagnosis and treatment of mental disease. As Geddes Smith says, "It is because some psychiatrists have learned how to create a setting in which people feel free to be themselves, and in which people can with help begin to work out their own problems, that they have something important to give to public health. This gift is not confined to psychiatrists; many people—including many health officers—have it naturally. But public health has taken small account of it even when it was instinctively practised by health workers, and the color which it gives to specific dealings with patients differs from that of ordinary health department procedure. Where dynamic psychiatry is permissive, public health is more apt to be instructive, didactic, sometimes even coercive. Its philosophy, a seasoned public health worker said at the institute is that of telling the patient what to do about something." Whereas, the psychiatric interview

("The giving of psychological support through listening") attempts to relieve and reassure, to make the patient feel at home, to give him opportunity to talk about what really troubles him.

It is obvious that this mental hygiene viewpoint is of major importance in the day-by-day activities of the health department. To quote again from Geddes Smith, the discussion of the institute "seemed to indicate agreement that respect for the human personality and some understanding of it, some feeling for people as individuals, can make everything a health department does for people more effective; that the health department, dealing with people in critical periods of their lives—childbearing, early infancy, chronic disease—has a superb opportunity to foster their mental health and so to render a truly 'preventive' service; that the health department shares with the whole community responsibility to provide facilities for the treatment of mental disorders; and that if a health department is fortunate enough to employ a well qualified psychiatrist or psychiatric social worker it is better to use him in training its own staff for their everyday jobs than in treating the mentally ill."

Finally, it seems clear that the approach emphasized at Berkeley has profound implications—not only with regard to contacts between the health department and the public, but also with respect to relationships between the staff members themselves.

The health officers at the institute were quick to realize that the same principles of approach which are effective in dealing with clinic patients carry over into staff relationships and relationships between the health department and the community. From the very first day the administrators began translating everything they heard into administrative terms. They knew that the hierarchy of the large health department creates tensions between staff workers, and that the more intimate community contacts of the small department call for the utmost skill. As soon as the principles of a good interview were brought to their attention they realized that these principles were pertinent in picking staff members and adjusting friction between them, in relieving their anxieties, even in discharging staff members gracefully. As they talked about these matters the health officers took the opportunity of ventilating many of their own characteristic anxieties: their frustation when they are caught between their own desire to do the best job they can and the niggardliness of appropriating bodies; their tensions in dealing with practising physicians; their discomfort in their relations with health educators; the uncertainties associated with work financed by federal funds; the interferences with direct action that come from pyramidal organization on the one hand and civil service on the other. They knew that if they were anxious, their associates were anxious too; and realizing that from morning to night the bulk of their work was done by and through interviewing of one sort or another, they were glad to understand better what they were doing and failing to do with this tool of relationship.

The effect of Dr. Zimmerman's early spade work in the California State Department of Public Health is well illustrated in Ann Wilson Haynes's description of the Inservice Training Program of the department presented at our Boston meeting.[3] Mental hygiene begins at home, in the staff of the health department itself; and California has shown us how the job can be attacked.

THE AMERICAN BOARD OF PREVENTIVE MEDICINE AND PUBLIC HEALTH

READERS of the JOURNAL[1] will have noted that a specialty board of Preventive Medicine and Public Health has been established, after incorporation, and with the approval of the Advisory Board on Medical Specialities and of the Council on Medical Education and Hospitals of the American Medical Association. It is now ready to operate.

The specialty board system goes back to 1917 when the Board of Ophthalmology was established. Within the succeeding three decades, 16 other specialty boards have been developed. It cannot be doubted that this movement has been a significant feature of medical education in the 20th century. It has rendered a most important service in setting standards for the improvement of medical practice and there has been continuing effort on the part of those responsible to establish a pattern of studious work and careful practice among physicians after they leave their interneship. It is reported by the deans of several outstanding medical schools that a large proportion of their graduates, in some cases as many as 90 per cent or more, are planning to complete the requirements for one or another specialty before undertaking practice. The resulting demand on residencies in clinical specialities has been a notable feature of the post-war period.

There are no doubt certain serious problems raised by this generally admirable development. It is inevitable that a major proportion of the need for medical care falls in the area of general unspecialized practice; and it is perhaps fortunate that some medical schools appreciate this fact. If medical practice in the future is to have a majority of physicians limiting their practice to a specialty, especially if these men on the whole tend to be the cream of the crop, it will be conceded that only those communities of larger size, say 25,000 and up, can expect to be equipped with physicians in a majority of the specialities. The resulting disadvantage to small town and rural community practice is manifest, and the specialty board system, by and large, is tending to make more difficult the task of getting more service out at the grass-roots.

Among the solutions offered for this dilemma we may note the concept of some of those identified with the specialty board for Internal Medicine who believe that the general practitioner of the future should be a qualified man in this specialty. Another possible solution is that all certified specialists should limit their practice to persons referred to them by other physicians, a system much more frequently followed in Great Britain than in the United States.

The specialty board program, in any case, is now well established as a national policy in the United States; and the necessity of providing for public health as a medical specialty is obvious. In the past, physicians operating as health administrators in government service have been seriously handicapped in financial status and prestige by the lack of specialty board status.

Public health physicians have need for closer links with clinical medicine and they believe that the practice of public health represents a specialty which deserves recognition with other medical specialities. They have made their case and we shall now have an opportunity to observe how the proposal works in practice.

The specialty board in Preventive Medicine and Public Health will provide a tangible measure of competence in our field. A mayor or a governor who wishes to select a health officer will now have an objective test of the training

and experience of a given physician. At its best, this Specialty Board will crystallize more sharply the qualifications of those who really are competent. It will probably result in a wider recognition in professional circles of the fact that public health is no longer an area where those who cannot make a success of other practice can find their life's work.

The work of the specialty board will be greatly facilitated by the fact that public health during the last three decades has developed the most thorough graduate course available in any of the specialities, none of which enjoys the academic recognition that has come to public health, and none of which can present an educational system which compares with the ten accredited schools of public health. The established accreditation system under A.P.H.A. auspices fits hand in glove into this picture.

The fact that public health in North America now has the benefit of a well developed system of modern examination methods also makes it more readily possible, in this field, to discriminate between the qualified and the unqualified than in any other specialty (although the specialty board for Internal Medicine has also begun to use objective type examinations). The Merit System Service of the American Public Health Association, however, during the last eight or nine years has developed about 20,000 objective questions in this field and an experience which approaches 500 examinations of public health personnel.

If this specialty board in Preventive Medicine and Public Health is to operate successfully, it will, however, require a very substantial improvement in field training areas which must compare in quality with the facilities for residency training in clinical specialities. Fortunately our Committee on Professional Education has anticipated this need through the publication of an important report on this subject.[2] It may be expected that the influence of the specialty board will have a favorable effect on these training facilities, as has been manifest in the area of hospital residencies.

It is already apparent that hundreds of younger physicians will seek to establish their qualifications in public health through the channels of this board. It is fortunate that the board has been established under auspices that include, beside the American Medical Association, those of the Canadian Public Health Association and the American Public Health Association. The board itself is off to a good start with excellent leadership.

MENTAL HEALTH ON A GLOBAL SCALE

IT is gratifying to note that the Executive Board of the World Health Organization at its March meeting approved the first world-wide program for mental hygiene ever to be undertaken on an international scale. Along with environmental sanitation, control of cholera, tuberculosis, and venereal diseases, and promotion of maternal and child health, mental hygiene is endorsed as one of six major projects to be undertaken in 1950; and a budget of $942,550 has been recommended for the mental health program.

In view of the prominence given to mental health in the WHO Constitution,

this action does not come as a surprise. Yet it is a source of gratification that interest in mental health is no longer to be limited to pious platitudes but is to take shape in action.

The program recommended to the WHO includes the following elements:

1. The organization of the Mental Health Section of WHO so that it may assist in the collection and coördination of all the existing data on the problems and facilities for mental health work throughout the world.
2. The provision of multi-disciplined teams for investigation of mental health problems, particularly amongst rural communities. It is suggested that one of the teams should be working in conjunction with the Mother and Child Health Project of WHO, whilst another one should be coördinated with the survey work of UNESCO and FAO.
3. Research teams working on mental health in industrial communities.
4. A team investigation in the field of student mental health, carried out not only as a reconnaissance but also as a demonstration.
5. Multi-disciplined teams sent to give demonstrations of methods of survey and prophylaxis.
6. Education experiments amongst existing WHO field teams, public health administrators and mental health workers. Long and short term fellowships in the mental health field to be encouraged.
7. Demonstration project in education of the public.
8. The establishment of an expert committee on mental health working for WHO and the building up of a multi-professional team for its own mental health staff.

It is our earnest hope that the project as outlined will be approved at the second World Health Assembly to be held in Rome next month and that the necessary funds may be appropriated to carry it out. The sum allotted is less than one-fifth of the total WHO budget; and this seems modest and reasonable. It is more than time that we recognized, in actual practice—what we all know in theory—that mental and emotional problems contribute a good half of the total burden of disease and disability.

JOHN J. SIPPY

THE death of John J. Sippy on March 15, has removed one of the outstanding leaders of administrative public health.

Born at Venice, Ill., in 1879, Dr. Sippy took his medical degree at P. & S., St. Louis, in 1899. He practised medicine in Kansas for thirteen years (serving also as health officer of Sumner, Kans., from 1908 to 1913). He became epidemiologist of the Kansas State Department of Health in 1913 and held the same position with the Montana State Department from 1919 to 1922, and served as director of child welfare in that department from 1922 to 1923.

The opportunity for his real life work opened up in the latter year. San Joaquin County, Calif., had been visited by a severe epidemic of diphtheria; and its residents decided to take advantage of a half-forgotten California statute which—since 1917—had permitted the establishment of full-time district health departments.

The preliminary steps to create such a district were taken and Dr. Sippy was named as health officer. The County Board of Supervisors belatedly discovered that valuable patronage was to be snatched from their clutches and brought suit to test the constitutionality of the enabling Act—which temporarily stopped all appropriations for the support of the new department. Led by Rotary Clubs in the major cities an extraordinary uprising of citizen interest was developed. The organizations concerned raised by popular subscription the funds to carry the department for eight months (until the basic legislation received final approval);

and Dr. Sippy and his staff carried on with personal drawing accounts from this fund.

When the battle was finally won, Dr. Sippy built up in San Joaquin County the first district health unit under the California law and developed a program of such excellence that Stockton in the late 20's was a Mecca for visitors who wanted to study a sound county health machine. His patient and determined spirit was manifest in every detail of the department; and members of the staff still vividly recall his routine daily rounds which involved at least a brief contact with every member of the team.

Dr. Sippy joined the American Public Health Association in 1919 and was elected a Fellow of the Health Officers Section in 1930. He served as President of the Western Branch in 1941 and was elected President of the American Public Health Association in 1943—the first President of the Association to be drawn from the vitally essential group of district and county health officers. He represented public health at the grass-roots, and public health of a quality to inspire the admiration of the profession throughout this continent.

Credit Lines

THE COMMUNITY HEALTH COUNCIL STORY IS BEING TOLD

The Division of Public Health Education of the Nebraska State Health Department, whose Director is Nina B. Lamkin, has prepared in mimeograph form some 15 pages of questions and answers about health councils. The record is set straight at the outset by stating that the ultimate goal is more local health departments in Nebraska.

This is a homey, practical document that suggests what health needs might be found in a community, names of organizations that should be brought together in organizing a community health council, and mentions existing Nebraska examples of the types of health councils discussed. Its definition of a local health department is "an organization set up in any city, county, or district at the request of the people to give them public health protection: to help them in defining their public health problems, and in utilizing all community and state resources in doing something about them."

The Iowa State Health Department has prepared *Iowa Health Council Plan* along similar lines. This includes, besides the step by step instructions for organizing a council, a suggested constitution and a report of a survey of public health resources in Iowa made jointly by the State Federation of Women's Clubs and the Department of Health. The study concludes that there is an almost complete lack of public health services at the local level and recommends that the federation cooperate in bringing about adoption in the 1949 legislative session laws necessary to permit establishment of satisfactory health departments.

The Kansas State Health Department has put its community health council lesson in a beautiful Chinese red pamphlet that defies indifference. Nor does the material inside disappoint expectations. Its last word is that no community can afford to be without the services of a local full-time health department.

KEEPING LAW MAKERS INFORMED

The Kansas State Board of Health has prepared for the 1949 State Legislature a digest report of its activities for the biennium ending June 30, 1948. It is a very well put together report that assumes maturity and intelligence in the state legislators. Facts are given straight with a minimum of self praise. The material is illustrated with a number of graphs.

U. S. VS. BRITISH PLUMBING PRACTICES

"Plumbing in America," by F. L. Barrow, and published by His Majesty's Stationery Office, London, describes the differences in plumbing practices as seen by Mr. Barrow during a trip of several months in the United States, and as practised in Great Britain. The report gives a useful review of practices in the United States. The price is 6d.

STARTING A MEDICAL CARE PROGRAM RIGHT

It will be remembered that the City of Baltimore recently asked to have the medical care program being carried on in the rest of Maryland extended to the city. The new city program carried on by the health department is limited to recipients of public assistance. In opening this service the health department has published a medical care

pamphlet telling recipients just how the program works and what they need to do to make it most effective.

AFTER A REPORT—ACTION

The *Brown* (Esther Lucille, Ph.D.) *Report on Nursing for the Future* has been out since late summer of 1948. In January, 1949, a flock of agencies in Indiana—the State Board of Health, State Nurses' Association, the division of nursing education of the State University, the State League of Nursing Education, and the State Board of Nurse Examiners—coöperated in a three day workshop designed to answer the question as to what Indiana should plan in relation to the report. The recommendations, too detailed for analysis here, are available from Helen J. Weber, Division of Nursing Education, Indiana University, Bloomington.

THE EPIDEMIOLOGY OF SYPHILIS

The Social Hygiene Committee of the New York Tuberculosis and Health Association has made available reprints of *The Epidemiology of Syphilis.* Written by E. Gurney Clark, M.D., Chairman of the Committee on Epidemiology of the Association of Syphilis Clinics, this article appeared in the November, 1948, *Journal of Medicine.* The Chairman of the Social Hygiene Committee is Frank C. Combes, M.D., and of the Association of Syphilis Clinics, Howard Fox, M.D.

The reprint is available in limited quantities from the Social Hygiene Committee, New York Tuberculosis and Health Association, 386 Fourth Ave., New York 16. Jacob Goldberg is the Secretary of this committee.

ANNUAL HEALTH REPORT AS NEWSPAPER ADVERTISING

The Lawrence-Wabash Health Department, with headquarters in Lawrenceville, Ill., presented its report for 1948 in the form of four advertising lay-outs headed respectively "Action for Health," "Polio—The Pearl Harbor of Public Health," "Declaration of War on Disease," and "The Atomic Bomb of Public Health."

According to the announcement of the County Board of Health, of which Roy R. Rucker is President, it was decided to select the six newspapers of the two counties in order to give a reader circulation in excess of 50,000 persons at what was said to be the same cost as the conventional report separately printed which would at best reach only a few thousand circulation. Dale E. Scholz, M.D., M.P.H., is the Director of the bi-county department.

SCHOOL DISTRICTS CONSOLIDATE

The 1947 Legislature of Illinois passed a community unit school district act which was recently upheld by the state supreme court. As a result school elections had already in the fall of 1948 reduced the 12,000 school districts in the state to 7,500 with the expectation that the number would be reduced to 3,000 by mid-1949. Fewer than 1,000 are recommended by county survey committees.

Several other states have enacted laws for the reorganization of school districts, a number of them passed by the 1949 legislative sessions. A distinguishing feature of these laws is the provision of a state commission and county committees to plan for school district reorganization and to set definite time limits within which plans must be acted upon.

ALCOHOLISM—A PUBLIC HEALTH PROBLEM

Evidence mounts that public health, and indeed medicine, now recognize that chronic alcoholism is also their province and not that of the penologist alone. The latest such evidence is the January, 1949, issue of *Health News* of the New York State Department of Health. This has an editorial on The

Problem of Alcoholism, an article on Chronic Alcoholism: A Public Health Problem, by Anton J. Carlson, M.D., and Joseph Hirsh, President and Executive Director respectively of the Research Council on Problems of Alcohol, as well as an outline of the program of the Committee on the Problems of Alcoholism of the State Medical Society by its Chairman, Milton G. Potter, M.D. It reports that 8 states have within the past 3 years established permanent programs to cope with alcoholism and that several others are expected to do so in the 1949 legislative sessions.

WHAT THE MENTAL HEALTH ACT MEANS

Printed in black, white, and restful green, *The National Mental Health Act and Your Community,* in 16 pages and a few charts, tries to tell each citizen what the Mental Health Act passed by the 80th Congress means to him and his community. The watchwords are prevention and working together. There is a foreword by Oscar Ewing, Federal Security Administrator. U. S. Gov. Ptg. Office, Washington, D. C., 10 cents.

BALTIMORE FIRST TO TELEVISE HEALTH

What is reported to have been the first health department television program was carried on in Baltimore during the past winter. In a series of weekly programs, the various aspects of disease prevention were televised. Coöperating with the City Health Department were the Medical and Chirurgical Faculty of Maryland and the State Medical Society.

30 YEARS OF CHILD HEALTH IN NEW JERSEY

Thirty Years Progress in Maternal and Child Health, by Julius Levy, M.D., Chief of the Division of Maternal and Child Health, New Jersey State Health Department, has been reprinted from the *New Jersey Public Health News.* It summarizes the not inconsiderable progress made in saving infants in that state since 1919 when the Maternal and Child Health Division was started. The infant mortality rate, for example, was 84.7 in 1919, 28 in 1947. Available from New Jersey State Department of Health, Trenton.

A NEW HEALTH COUNCIL PUBLICATION

Health: Everybody's Business began publication as the monthly organ of the Health Council of Greater New York in February. In four pages of mimeographing it had capsule stones of health and Health Council News of New York City. Health Council of Greater New York, 130 East 22d St., New York 10.

SCHOOL HEARING CONSERVATION PROGRAM

During most of the school year 1947–1948, the Illinois Commission for Handicapped Children, through its Advisory Committee on Hearing Conservation and Rehabilitation, carried on a Hearing Conservation Program in the public and parochial schools of Will County. This county of about 115,000 population was chosen because it has both urban and rural schools and has an organized full-time county health department. This was in effect a pilot project to develop experience for a hearing conservation program throughout the state.

In the program more than 20,000 children in 188 schools were given audiograms. About 8 per cent were referred for otological examination.

The report of this project has been printed by the Illinois Commission for Handicapped Children, 160 North La Salle St., Chicago 1, from which it is presumably available.

NATIONAL HEALTH COUNCIL DIRECTORY

The National Health Council recently issued the 1949 directory of its 23 member organizations. Not only does it

have excellent summaries of the goals, programs, and services of each of the 23 agencies, but also a brief historical sketch of the Council itself together with an outline of its purposes and present programs. "The aim of the Council," says the brochure, "is the strengthening of the public health movement, both official and unofficial, through common planning and action of its members and through development of widespread citizen participation in and support for measures that will help the individual maintain maximum mental and physical health." Perhaps that is another way of saying, "Lets get on with the goals on which we are in common agreement."

National Health Council, 1790 Broadway, New York 19. Single copies, 25 cents; 25–49 copies, 20 cents each; 50 or more copies, 15 cents each.

LIONS SHED LIGHT ON A SCHOOL

The Lion's Club of New Kensington, Pa., found a dramatic and highly practical way of carrying out its national program of aiding the blind and conserving the sight of the young. About two years ago it underwrote the cost of relighting one classroom of the New Kensington High School. The installation of fluorescent and louvered fixtures raised the lighting level and provided comfortable, glare-free conditions throughout the room.

After a year's experience, school authorities and parents saw the sense and economy of making seeing easier in the classroom, and the entire school lighting has been modernized. Another example of a voluntary agency showing the way.

METROPOLITAN LIFE STATISTICAL BULLETIN AVAILABLE TO HEALTH WORKERS

Credit Lines, reviewing the contents of the *Bulletin* for the last year, notes the pertinence of the topics discussed for health departments and voluntary agencies and points out the utility of the month-by-month record of mortality experience among the Metropolitan's millions of policy holders as a readily available base line against which local observations can be checked. No other summary of mortality is available for a large group so promptly.

Among the topics important to the health professions in the last volume of the *Bulletin* may be mentioned observations on regional population growth, the marked decline in fatal accidents among women, conserving the life and health of preschool children, health conditions in Europe, malaria being wiped out, high accident death toll among preschool children, smallpox almost eradicated, on the confidential reporting of causes of death, improvement in cancer mortality among women, further progress in longevity expected, and on making maternity still safer.

The *Bulletin* is available for free distribution from the Metropolitan Life Insurance Co., 1 Madison Ave., New York, N. Y.

OCCASIONALLY SCREAMING DOES IT

The first step in overcoming one's faults is to recognize them, it has been said. If so, Arizona is already started on the road to lower infant mortality and tuberculosis death rates, better cess pools and garbage disposal, and more extensive pasteurization of milk.

In the best scare headline tradition the *Arizona Times* of Phoenix for two consecutive days at the end of 1948 carried a number of articles telling what is wrong with the health picture of Arizona—the second highest infant death rate of any state in the union, the highest tuberculosis death rate (called the white plague of Arizona), an undulant fever incidence rate of as high as 5.8 per cent, water contamination by cess pools widespread, and garbage disposal nearly everywhere unsanitary.

That a state, which, as the paper says, bases its bid for tourists and winter

visitors largely upon its health-giving climate, should itself expose all these health hazards is to be commended. It should be noted, further, that Phoenix is not cited among examples of certain good conditions as Tucson and one or two other localities are.

The pay-off: The 1947 state legislature made a niggardly appropriation for the state health department in reply to the Governor's vigorous message demanding an appropriation adequate to meet the challenge. Reprints of the Phoenix articles have been circulated to all members of the 1949 legislature with the message, as it were, pigeonhole similar legislation this year, if you dare!

NEVADA NEWSMONGER BACK

The Public Health Nursing Division of the Nevada State Health Department used to have a publication called "Newsmonger." For 6 war and postwar years it fell by the wayside. As of February, 1949, it was revived as a quarterly and renumbered Vol. 1, No. 1. Its stated purpose is "to help the field nurses to maintain contact with each other and with the nursing programs in various stages of development in the various counties" and "to give a clearer picture of the functions and activities of the other divisions of the state health department." It also will give the state health officer opportunity "to express his own philosophy in regard to ways of adapting public health nursing programs to local facilities and circumstances."

CITY NOW PROVIDES BABIES' MILK

An evolutionary process begun in Baltimore in 1884 has now reached its goal in that the Baltimore Health Department has absorbed completely the work of the Babies Milk Fund Association of that city.

The association grew out of a summer hospital for babies opened in 1884. Formally incorporated in 1906, it had already several years before opened its first stations to provide milk, medical examination, and nursing instruction. In 1938, when the plan was made for gradual transfer to the health department, more than 13,000 babies were under care at 40 weekly clinic sessions in 28 stations.

In 1919 the health department established the first of its similar clinics and in January, 1949, after it took over the last of the Babies Fund Clinics, it was serving more than 20,000 infants in 81 weekly sessions at 42 well baby stations scattered throughout the city.

Two things are particularly notable for other agencies going through a similar evolutionary process:

a. The voluntary agency pioneered in showing the need and ways in which it could be met, but did not develop a "vested interest" in the service.

b. The transition from voluntary to official sponsorship was planned and gradual enough to avoid disruption of service.

REPORT ON "TAKE A TEST"

For those who visited and stayed to "Take a Test" in the Merit System booth at the A.P.H.A. Annual Meeting in Boston a complete report of that experience is now available. It includes the results of the tests, a set of the tests themselves, and a statistical analysis of the scores and questions. Six tests were offered. Some persons took more than one test, a few answered all the tests, and, in all, nearly 500 persons participated in the projects, or more than 10 per cent of those registered at the annual meeting.

More persons chose to test themselves in Facts, Foibles and Fallacies (a test of common misconceptions in the field of health) than in any other one field. The most difficult test, with 169 persons answering, was Grass Roots and Ivory Towers (Administration). When scores are broken down into age groups, years of experience, education, type of occupation, etc., for each test, there are

challenging revelations. For full appreciation of the results the report must be read in detail.

There are just as many interesting findings in the analysis of the items as in the differences described in the average scores obtained by the various categories of examinees. To disclose just one reassuring fact: 84 per cent of those answering the question know that it is now thought that physical hardships alone do not of themselves induce colds unless an infecting agent is present.

It may be a little disturbing to read that only 41 per cent of those taking the test with this question in it, knew that Samuel J. Crumbine, M.D., has recently written a book dealing with the early days of public health in this country. Other arresting findings await study.

The report as a whole offers a good example of the processes of testing adopted by the Merit System Service. Copies may be ordered from Merit System Service, American Public Health Association, 1790 Broadway, New York 19. $1.00.

PREVIEW OF CHILD HEALTH STUDY

With a very attractive pamphlet—*The Road Ahead for Better Child Health*—the American Academy of Pediatrics has whetted the appetites of those who await the full report of its monumental study of child health services. Published by the Commonwealth Fund, this has just come off the press and is ready for distribution.

The pamphlet picks up and dramatizes in charts or pictures some of the startling facts found by the study. The picture of the sturdy youngster trudging doggedly down the road of his future is not the least of the pamphlet's appeal. Available from the Committee for the Improvement of Child Health, 1740 Bainbridge Street, Philadelphia 46.

A PATIENT'S HISTORY FORM

Oliver E. Byrd, M.D., Ed.D., known to health workers for his annual *Health Instruction Year Book,* has prepared a *Patient's Self-History Form* for the use of physicians and hospital administrators. Designed as a time saver for the doctor, it is the patient's own inventory of his health history as he sees it.

The inventory is brief but inclusive, 8 pages in all. The patients answer questions under five main headings: family health, social history, hospitalization, work experience, and military experience.

The *Self-History Form* is published by the Stanford University Press, Stanford, Calif., from which it is presumably available.

ANNUAL REPORTS

Chicago's Human Responsibilities and How They Are Met is the title of the 33rd annual report of the Chicago Council of Social Agencies. Community responsibility is its theme carried out in photographs, charts, and a high quality of production. Chicago Council of Social Agencies, 123 West Madison St., Chicago 2.

Lorain County (Ohio) General Health District, 29th Annual Report. In accordance with what appears to be a current trend, this annual report is in the form of a weekly country newspaper — advertisements and all. It should be said first that this health district is made up of the rural areas of Lorain County, thus serving about 45,000 of the county's 112,000 persons. The remainder are served by two city health districts, Lorain and Elyria, each with part-time health officers. The county district report shows a well balanced program, a training program linked to schools of public health and to overseas visitors, and a well districted nursing program. Its articles are newsy in the journalistic tradition and its ad-

vertisements are uniquely thought provoking. For example, "Wanted: Experienced bartender who will coöperate with health department inspectors."

The financial figures show an expenditure for the basic budget (excluding the training program) of a little less than $1 per capita in 1948. Including the budget of the training center, met largely by Kellogg Foundation funds, expenditures were approximately $1.33 per capita.

The National Committee for Education on Alcoholism reprints its annual report from the December, 1948, *Quarterly Journal of Studies on Alcohol.* Perhaps its most revealing statistic is that in one year, the fourth of the committee's existence, local affiliated committees increased from 25 to 39, with 43 additional ones in formation (5 of these and 2 others not then contemplated have been formed since the report came out). These local committees are located in 27 states, the District of Columbia, Canada, and Mexico.

This report describes fully the work of the National Committee and provides thumbnail sketches of each of the local committees. National Committee for Education on Alcoholism, 2 East 103rd St., New York 29.

SOCIAL WORK YEAR BOOK TO BE CONTINUED

The Social Work Year Book, of which the 10th Edition, 1949, has recently been published by the Russell Sage Foundation, is to be carried on in subsequent editions under the auspices of the American Association of Social Workers. Margaret B. Hodges who edited the 10th Edition will continue as Editor of the *Year Book.*

WORTH ACQUIRING

Safer Ways in Nursing to Protect Against Tuberculosis is a guide for precautions in the care of tuberculosis patients. It was prepared for the National Tuberculosis Association by the Joint Tuberculosis Nursing Advisory Service. It should be particularly valuable for directors of nursing services in general hospitals, sanatoria and other voluntary and official public health agencies. Available from state and local tuberculosis associations.

Rheumatic Fever and the School Child is reprinted from September, 1948, *Pediatrics,* the journal of the American Academy of Pediatrics. It is a statement to guide school health authorities, prepared jointly by the Committees on School Health and Rheumatic Fever of the Academy of Pediatrics. Reprints are not available but there is blanket permission for its reproduction. *Pediatrics* office is at 325 N. Euclid Avenue, St. Louis 8, Mo.

Program Package for Home Safety is said to be for the doer communities who want an answer to the home safety problem. It is a guide kit for the planning and carrying out of a safety program by a community home safety program. It has ideas for a sample club program, news releases, radio talks, exhibits, surveys, etc. The kit sells for $1 or $2, including a year's subscription to the bi-monthly news bulletin and the *Home Safety Review.* National Safety Council, 20 N. Wacker Drive, Chicago.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

Dentistry in Public Health—*Edited by Walter J. Pelton and Jacob M. Wisan. Philadelphia: Saunders,* 1949. 352 pp. Price, $5.50.

In addition to their own contributions to *Dentistry in Public Health,* the editors of this long needed and long awaited volume have evinced a high caliber of editorship in numerous ways. Two of these are particularly noteworthy; first, the excellence of their selection of contributors and, second, the orderly fashion in which the material is arranged.

Even those who may feel that some other person might have covered better an assigned phase of dental health will admit that selected contributors rank high in any list to which the editors might have turned. Not only their names, but the excellence of their contributions give evidence of the care exercised in their selection.

The purpose of the book is probably best attested by the uniquely logical order in which the material is presented. Sequentially it carries public dental health from an initial sociological "setting" through all, or very nearly all, of its phases and ramifications. Hence, as a textbook for undergraduate dental students and dentists novitiates in the field of public health, or as a ready reference for the dental profession and public health personnel, it offers an amazing amount of data in a logical order.

Many accustomed to thinking of dental health programs as consisting of examinations and, possibly limited corrective care of the teeth, are apt to be amazed at the ramifications and intricacies disclosed on the problem in this book. To such readers the book should prove informative and interesting. However, as chapters such as those on Biometrics, Surveys, etc., will attest, the book is not meant for casual reading.

The bibliographical references give additional value to the book, as does its comprehensive index. Several noted errors in dates and typography are not sufficiently important to detract from an overall excellence.

RICHARD C. LEONARD

Understand Your Child — Ages 6 to 12—*By Clara Lambert. New York: Public Affairs Committee, Inc.,* 1948. No. 144. 32 pp., Price, 20 cents.

We have long needed this illustrated 32 page pamphlet, which was written primarily for parents of children from 6 to 12 years of age, the so-called "forgotten years of childhood." The author, for 12 years Director of Teacher Education at the Play School Association, shows real understanding and describes with charm and humor the behavior which is "six-year oldness," "seven-year-oldness," and so on. She has described the characteristic behavior and the "pack of worries" carried by normal children at 5 age levels, including 6, 7, 8, 9, and 10 to 12 years.

By describing the behavior and problems of normal children, the tensions and worries of parents may be relieved because of their understanding and willingness to accept children as they are. "Some Hints for Parents" are included with the advice that there is no rule of thumb to follow.

There is a place for this pamphlet in the school program, in parents' study groups, in the hands of the grade school

teacher, and public health nurse, as well as meeting individual parent needs.

RUTH J. RAATTAMA

The Story of Blood—*By John H. Glynn. New York: A. A. Wyn, Inc.,* 1948. 285 pp. Price, $3.00.

Dr. Glynn has used the central theme of the blood to provide a thumbnail sketch of many aspects of medicine and human biology. With the familiar device of tracing the main lines of thought which have resulted in modern concepts, he manages to convey to the layman a considerable amount of information on subjects ranging from abscesses to white counts, from arteriosclerosis to the effects of worry, from the adrenal glands to vitamins. In barely 60,000 words a surprising amount of accurate knowledge is clearly and simply presented. The approach is reminiscent of Paul de Kruif, minus the exuberance and hyperdramatics. In a more ideal society we might hope that the facts given by Glynn would be taught in every high school; as it is, we must hope that books like this will reach a wide audience.

ANCEL KEYS

Textbook of Attendant or Practical Nursing—*By Katherine Shepard (3rd ed.). New York: Macmillan,* 1948. 506 pp. Price, $4.25.

This is the third edition of a time-tested textbook originally published in 1935. Its material has been drawn from the experience of many years of teaching attendant nurses in the Household Nursing Association of Boston, enriched by new chapters on the care of the well child, the aged, the helpless and chronically ill patient. The revision has taken into consideration the Analysis of Practical Nursing issued under the auspices of the Vocational Education Division of the Federal Security Administration and is in accord with the curriculum prepared by the Approving Authority of the Massachusetts Board of Registration in Nursing. The book, therefore, represents authoritative statements in this field.

The character of the material in this textbook may best be described as sensible, practical, and simple. Its scope is definitely limited to the average capacity of a non-professional, non-scientifically-prepared individual who is learning to be an assistant to a professional nurse or to be in charge of those definitely not in need of professional nursing care or supervision. Special pains have been taken to include procedures of use in homes and hospitals and to adapt the material through simple language and familiar examples to the elementary *but skilled* level of nursing expected of the attendant.

All in all, instructors of attendant and practical nurses will find this a serviceable basic textbook on which to build their teaching. There will be need for reference to considerable recent supplementary reading for students in nearly all of the subjects presented because there is only one brief list of reading suggestions for the student. Perhaps this is as well, since it is difficult to keep lists of health education and visual aid materials up-to-date.

DOROTHY DEMING

Irregular Discharge—The Problem of Hospitalization of the Tuberculous. *V. A. Pamphlet 10–27 Washington: Veterans Administration,* 1948. 64 pp. Price, S.20.

This is a penetrating inquiry into the perplexing problem of irregular discharge among tuberculous patients in all V.A. and "Non-V.A." hospitals in which veterans were housed during the month of July, 1947 (irregular discharge is defined as any discharge of a patient from a hospital without professional medical sanction).

The study comprises: analysis of incidence of irregular discharge; analysis of basic causes of irregular discharge,

including components of social and psychological significance; summary analyses of earlier studies; and well considered recommendations for preventive measures based on findings.

The approach is unique in comparison to previous studies in that (1) patients were interviewed not earlier than three months after discharge (October, 1947–December, 1947), when reason was more likely to replace emotion; (2) interviews were made by experienced personnel "who would have no reason to regard the irregular discharge as a reflection upon their professional competence." Furthermore, since the Veterans Administration constitutes the largest single hospital system in the United States, there was a greater opportunity for validity of comparison among hospitals over a wide area than could otherwise be obtained.

The study is well annotated with supporting bibliography. A scientific document of distinct value, it should prove of interest to anyone concerned with tuberculosis control.

ROBERT W. OSBORN

Manual for Medical Records Librarians—*By Edna K. Huffman. (2nd rev.) Chicago: Physician's Record,* 1948. 357 pp. Price, $4.50.

The second edition of a popular book first published in 1941 has been revised. The material is well arranged and concisely written. Two new chapters on Interdepartmental Relationship and Group Studies have been added. The chapter on Organization and Management has been expanded and includes discussions of the Relationship of Medical Record Librarians to the Administrator, Work Plan, Chart of Organization, Job Analysis and Procedure Manual. The section of Microfilming and Punched Card Methods of Indexing and Cross-Indexing have been rewritten and a good topic on Medical Illustration Index has been added. There is a greatly enlarged reference of medical terminology — stems, prefixes, suffixes, abbreviations, homonyms, drug and hospital terms. A selected bibliography of medical records literature 1929–1946 is appended. A good index concludes the book.

The vast experience of the author in the medical record librarian field lends validity to this volume. It is a book that is recommended to all who are interested in elevating the standards of medical records. MAUDE MARIE HOLMES

Medical Writing—*By Morris Fishbein. (2nd ed.) Philadelphia: Blakiston,* 1948. 292 pp. Price, $4.00.

This second edition of this American classic on the writing of medical manuscripts is to be commended to all and especially to those who are beginning to write papers. This very readable book includes such important matters as style, construction of the manuscript, bibliographic material, illustrations, tables and charts, proofreading, indexing, and abbreviations of names and periodicals.

REGINALD M. ATWATER

Progress Report of the Chicago Venereal Disease Control Program —*July 1, 1943 to October 31, 1947. Chicago: Chicago Board of Health.*

This 41 page, loose-leaf, glossy paper pamphlet may fairly be described as a promotional medium of a type which is common in the commercial field but of comparatively recent vogue in public health. If a report to the stockholders of the corporation is a sound investment, then this factual accounting to Chicago's citizens should promote confidence and understanding of the city's venereal disease control program.

The section of this report devoted to the central registry describes the means by which the administrative center managed the voluminous correspondence involved in handling as many as 12,821 VD reports in 1944, as well as epidemio-

logic reports and follow-up letters to persons suspected of venereal disease and those who had been treated, reaching a peak of 13,788 letters in a 12 month period in 1946 and 1947.

The report of the epidemiology section describes the evolution of the contact-tracing methods. Because of the nature of this report, there is no detailed description of the organization of patient-interviewing and contact tracing, which were carried out by separate units of the VD division. Emphasis is laid upon the results of the use of the telegram to persuade suspected persons to *come into the clinics.*

In the clinic, intensive treatment center and laboratory sections, the statistical data which document the great volume of work done in Chicago during this period are presented so simply as to permit understanding without special knowledge of the program.

The record of the education section, particularly in the 45 day public education program in 1947, is particularly inspiring. A great number of educational units was distributed. The fact that 54 per cent of almost 10,000 "observations" made during the campaign were volunteer patients seems to demonstrate the value of the methods utilized.

There are four cuts and four pages of statistical charts which tend to enliven rather than burden this report. Though not a suitable source of detailed statistical material, as health department reports tend to be, the results in terms of public support of the Chicago VD program should be considerable.

JAMES H. LADE

Symposia on Nutrition, Volume I, Nutritional Anemia—*Robert Gould Research Foundation, Inc., Cincinnati,* 1948. 194 pp. Cloth.

This volume is made up of a series of eleven papers prepared for a Symposium on Nutritional Anemia. The symposium was organized by the Robert Gould Foundation and was held in Cincinnati in October, 1947, under the auspices of the College of Medicine of the University of Cincinnati.

The papers deal with different aspects of nutritional anemias, including relationships of folic acid, iron, copper, vitamin B complex, and vitamin C, to these anemias in infants, children, and adults. The presentations are correlated in such a manner that chemical, physiological, and clinical phases of nutritional anemias are stressed.

This collection of papers is a valuable addition to the literature on nutritional anemias, representing much original research on the part of the authors and their colleagues. This symposium will, no doubt, help to stimulate a better understanding among workers in this and related fields. The book was published August 15, 1948. It is distributed without cost to individuals and organizations interested in nutrition problems.

WALTER WILKINS

Convalescent Care for Children—*By Kathleen Allen, Director of Study. Chicago: National Society for Crippled Children and Adults,* 1947. 158 pp. Price is not reported.

In 1942 the National Society for Crippled Children and Adults published a *Directory of Hospitals and Institutions for Chippled Children.* Recognizing the fragmentary nature of information on convalescent services for children, and in accordance with a broad interpretation of the Society's purposes, it initiated a study of such services in 1944. A committee headed by A. L. Van Horn, M.D., then Assistant Director of the Division of Health Services, U. S. Children's Bureau, supervised the study.

The report includes detailed plans, including architects' drawings, for convalescent homes; a selected bibliography; a list of homes by states; a list

of state services for crippled children, and a list of the state member societies of the National Society. This is an excellent source book of information on convalescence for children.

MARTHA LUGINBUHL

National Conference on Undergraduate Professional Preparation in Health Education, Physical Education and Recreation — *May 16–27, 1948, Jackson's Mill, W. Va. Chicago: Athletic Institute,* 1948. 40 pp. Price, $1.00.

This was a national conference sponsored by nine national associations. The report of the conference includes the responsibilities of the colleges and universities for the preparation of teachers and leaders in health education, physical education and recreation. The conference prepared a special report which was published by The Athletic Institute and distributed by them at cost.

The *general education* that all persons attending college should have to become good citizens was outlined. The report also specified the *general professional education* needed by all teachers. The demand for teachers and leaders in these fields was also pointed out.

The major part of the report is devoted to the special professional preparation needed by teachers in health education, in physical education, and in recreation.

The functions of health teachers in the instructional program, in healthful school living, and in health services, are presented to guide professional educational institutions in the preparation of teachers and leaders so that they will be able better to meet the needs of children and youth.

FRANK S. STAFFORD

Survey Report, Department of Health, Pittsburgh, Pa. *Washington: Public Health Service, Federal Security Agency,* September, 1948. 385 pp.

The thorough study of which this is the report can be of inestimable value in obtaining more and better public health for citizens of Pittsburgh. An invitation to appraise the official health activities and make recommendations for their improvement had come from Mayor Lawrence and Dr. Norris W. Vaux, Secretary of Health of Pennsylvania. Thirteen committees of citizens, working in as many aspects of Pittsburgh's public health, reviewed the findings, and discussed the recommendations. The study was closely allied with the Federation of Social Agencies.

While the importance of health services in neighboring communities and in other agencies is fully recognized, in general the report necessarily covers the health facilities of the Pittsburgh Department of Health. The survey was made under the personal direction and supervision of Dr. Erval R. Coffey and 18 physicians, nurses, engineers, health educators, statisticians and personnel and administrative experts also participated. The Children's Bureau was responsible for the Maternal and Child Health chapter.

The usual outline for each chapter is a brief discussion of principles, the critical report of the program in Pittsburgh and recommendations for improvement. The summary of recommendations contains eight items suggesting a simplified organization, an advisory council, the active application of good personnel practices, a codification of the laws, the development of a decentralized program, coördination with other communities and agencies, and adequate funds. The chapters, of course, contain excellent and detailed consideration of each program. The chapter on mental health is a welcome addition to public health studies and is particularly well prepared.

Pittsburgh's commendable progress is well recorded in the report and substantial acceleration has already been achieved.

ROSCOE P. KANDLE

Food Plant Sanitation—*By Milton E. Parker. New York: McGraw-Hill,* 1948. 447 pp. illus. Price, $6.00.

This volume, one of a series in food technology, presents the specialized application of the principles and practices of sanitation to the food processing field. It undertakes to provide answers to some of the problems developed by the rather severe impact of the revised Food, Drug, and Cosmetic Act on a previously indifferent food industry. The philosophy and the related managerial aspects of food plant sanitation are set forth with commendable clarity. The chapter on rodent control is the least satisfactory, but two chapters on Fungicides, Germicides, and Sanitizers, and on Effective Detergency are extremely useful. For the many without training in the field of sanitation who are being forced into responsibilities for food plant sanitation programs, Professor Parker's book supplies much of the needed information, and it should be on the reference shelf of every sanitarian.

J. LLOYD BARRON

Dairy Manufacturing Processes—*By E. L. Fouts and T. R. Freeman. New York: Wiley,* 1948. 237 pp. Price, $3.50.

This book is designed basically to give the dairy plant operator and his employees practical information on the processing of milk and the manufacture of related products. The constituents of ice cream and the formulation of them are discussed in a most useful manner. Processing problems involving market milk, chocolate milk drinks, cultured buttermilk, and homogenized milk are covered. Butter making, soft cheese manufacture, and the more commonly applied tests for dairy products are included in the text.

Under each classification of product the authors have organized and arranged their material alphabetically for ready and easy reference. The book is very practical in content, avoids discussions of theory and should serve as a valuable and useful handbook for those engaged in the several phases of dairy products manufacture.

HAROLD S. ADAMS

Handbook of Dental Practice—*Edited by Louis I. Grossman. Philadelphia: Lippincott,* 1948. 417 pp. Price, $12.00.

This is an interesting and well balanced reference book on the most modern methods of the practice of dentistry. Dr. Grossman has assembled articles by some of the foremost practitioners and teachers in the field of dentistry, and has divided the *Handbook* into two parts. The first part covers diagnosis and treatment, with chapters on prevention and control of dental caries, roentgenologic interpretation, orthodontics, periodontics, endodontics, diseases of the mouth, prescription writing, anesthesia, and exodontics. The second part covers restorative dentistry, with chapters on gold inlay, amalgam, and silicate restorations, ceramic restorations, pedodontics, crown and bridge restorations, and partial and complete dentures.

It may be seen from the above listing of chapters that there is no specific section on public health dentistry and its problems. However, the first two chapters, The Prevention of Dental Caries and Control of Dental Caries, deal with the present status of prevention and control of caries from the community standpoint so that the subject has not been entirely neglected.

The Handbook is intended primarily for the practising dentist. Its object is to give him concise description of the various technics used in dental practice and an understanding of dental disease and its treatment. The reader will do well to supplement the practical details described by reference to more complete texts where necessary.

WILLIAM F. LEONARD

Technique of Treatment for the Cerebral Palsy Child—*By Paula F. Egel. St. Louis: Mosby,* 1948. 203 pp. Price, $3.50.

This able book is a valuable addition for technicians who are engaged in this challenging but as yet pioneer field of endeavor. In the care and treatment of cerebral palsy there is no unanimity of agreement on clearly defined standards and it is well to have texts giving different approaches to this problem. Miss Egel's handbook, designed primarily for technicians who carry out treatment for cerebral palsy patients under qualified physicians, fills a need as a reference for the expanding corps of trained persons working with the cerebral palsy child. The treatments outlined in the book are based on those prescribed by Dr. Winthrop M. Phelps, an outstanding authority in the field of cerebral palsy, under whom the author worked and gained invaluable knowledge which is now made available to others similarly engaged. The author's work has been limited almost exclusively to cerebral palsy children, and she possesses first-hand knowledge of the problems of those in special institutions for rehabilitation as well as those cared for at home.

The treatments as outlined in the text for the various types of cerebral palsy are presented in an orderly fashion, with an excellent summary at the end of each chapter, making the book especially valuable to those of limited experience who are encountering problems for the first time. The text outlines fifteen modalities by Dr. Phelps used in treating the different types. The exercises for conditioned motion described in the text are timed to rhymes and music and are accompanied by numerous sketches for clarification of these procedures. This section is of service to mothers and others with practical experience in the field but who are in need of guidance.

Finally the book contains an excellent chapter on equipment and apparatus which makes it a valuable guide to those responsible for organizing and developing a center for cerebral palsy children. The appendix gives a splendid account of the physical organization of the Cerebral Palsy Department in the Buffalo Children's Hospital and discusses results obtained and outlines the place of parent groups in the overall program.

The book is recommended as a valuable guide for technicians who work with cerebral palsy children.

HARRY B. SMITH

Pediatrics and the Emotional Needs of the Child—*By Helen L. Witmer, Editor. New York: The Commonwealth Fund,* 1948. 180 pp. Price, $1.50.

This booklet describes what took place during a three day conference when a group of pediatricians (most of these also administrators and teachers), child psychiatrists, social workers, and the medical staff of the Commonwealth Fund discussed the incorporation of mental health principles and knowledge into the teaching and practice of pediatrics. With the exception of four outstanding lectures on the general topic of "What have we learned about emotional growth and development?" which opened the conference, the remainder of the material is presented as an almost verbatim discussion by the participants. The discussion centered around the topics of mental health in pediatric practice, the training of medical students and pediatricians, and hospital practice and research. The book presents not only a wealth of information relative to these subjects not found in any other literature, but because this information is largely the result of personal experiences of the participants, described in their own words, something else is portrayed. The reader feels himself a part of the dynamic group experience that in the three days encompassed curiosity,

difference of opinion, resistance, identity of purpose and concept, and clearer delineation of the problems still to be solved. The book should be indispensable to teachers of medicine and nursing, directors of maternal and child health programs, and valuable to practising physicians. KENT A. ZIMMERMAN

Childhood Mortality from Rheumatic Fever and Heart Diseases—*By George Wolff. Washington: Federal Security Agency, Social Security Administration, Children's Bureau. Publication 322,* 1948. 63 pp. Price, $.25.

This study of differential mortality covers all of the states and is based on data for a three year period so as to reduce chance fluctuation.

Principal findings may be briefly summarized: (1) If one disregards accidents, rheumatic fever and heart diseases play an increasing part among the leading causes of death in children of school age and youth, particularly in the white population (tuberculosis is still a more important cause for the non-white group); (2) The non-white children show in all age groups higher mortality rates than the white children throughout the states, with few exceptions in the mountain division; (3) Sex differences are not important except in the group of adolescents from 15 to 19 years of age. At this age the white boys show higher rates than the non-white boys.

This is an excellent example of a well focused study which deserves the attention of those concerned with child hygiene and with epidemiology.

REGINALD M. ATWATER

Textbook of Public Health—*By W. M. Frazer and C. O. Stallybrass. (12th ed.) Baltimore: Williams & Wilkins,* 1948. 571 pp. Price, $6.50.

This fine standard *Textbook of Public Health* (formerly Hope and Stallybrass) has now reached its twelfth edition. The book covers the ground both for the Certificate and the Diploma in Public Health in Great Britain and is especially designed for students of that nation. It contains a great deal of splendid material that is of general utility for all public health workers throughout the world.

The text emphasizes the administrative control of environmental factors, and their relationship to health protection. It has a fine section on epidemiology and an excellent chapter on vital statistics. Housing and town planning, hospital administration, social services, and port health administration are all given due emphasis. All the standard functional divisions of the health service, such as contagious disease control, control of venereal diseases and of tuberculosis; maternity and child welfare, school medical services, mental hygiene, etc., are discussed adequately. There is also a short but excellent chapter on genetics.

The text, we believe, should be on the shelves of all public health administrators as an excellent reference, and it is useful, as well, to teachers of medical students in the field of preventive medicine. W. G. SMILLIE

Viral and Rickettsial Infections of Man—*Edited by Thomas M. Rivers. Philadelphia: Lippincott,* 1948. 587 pp. Price, $5.00.

The appearance of this excellent book is a milestone in medical bibliography emphasizing, as its editor indicates, the stabilization of knowledge concerning the problem which has been acquired as work in the field has progressed. It is the first in the United States which has attempted to bring into one volume the large body of knowledge which has accumulated concerning viral and rickettsial infections. The book is directed primarily toward practising physicians and medical students rather than to those intensively trained in the technical

aspects of virus studies. There are 37 chapters by 27 authors. The first 5 chapters lay a foundation for subsequent treatment of the individual diseases by presenting first a general statement of current concepts of infection by these agents; this is followed by general chapters concerning technics especially applied in their study—physico-chemical, serologic, the use of chick embryos, tissue culture. The remaining chapters consider practically all the infections of man in which viruses and rickettsiae are implicated. The diseases are discussed in a rather uniform manner comprising history, clinical and pathologic pictures, experimental aspects of study and the character of the agent, diagnosis, epidemiology, and treatment. This last section takes little space.

Rather than following personal bents, the authors have achieved a good objective balance and, consequently, the book is of great value to students, clinicians, or investigators. To those in public health it serves to emphasize the practical desirability of an expanding participation by health departments and their laboratories in the study of the viral and rickettsial diseases.

Bibliographies are well chosen and the index is quite adequate. The price, owing to an effective subsidy, is also remarkably attractive.

THOMAS FRANCIS, JR.

Studies in Psychosomatic Medicine. An Approach to the Cause and Treatment of Vegetative Functions —*Edited by Franz Alexander and Thomas Morton French. New York: Ronald Press,* 1948. 568 pp. Price, $7.50.

This book consists of a collection of thirty-four papers which were written by the staff of the Chicago Institute for Psychoanalysis and which deals with the emotional factors involved in disturbances of the various vegetative functions.

The first part is concerned with general principles. The attempt to single out certain diseases as psychosomatic is considered erroneous. Rather, the expression "psychosomatic" is used as a term for that approach in medicine which involves "simultaneous study and treatment of psychological and somatic functions in their mutual interrelation." The concept that organic diseases may develop as the end result of emotional disturbances is discussed.

There are chapters on the functions of the hypothalamus and the physiological effects of psychoanalytic therapy. Later papers deal with particular systems. Several give summaries of the analyses on which conclusions are based. There is a laudable reticence to regard pioneer research as conclusive. The most disappointing thing about the volume is that many papers were written a decade ago, and one wonders whether the years have confirmed or changed their conclusions.

In general, the book is highly recommended to all physicians, public health workers, and those engaged in programs for medical care. The subject is important, the approach scientific, and the exposition clear. WILLIAM A. DAVIS

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

First Time—What soothing words could be added by way of annotation to the ominous threat hidden in the title that follows?

ANON. Women Now Outnumber Men. Stat. Bull. (Met. Life Ins. Co.) 30, 2:4 (Feb.), 1949.

"Proud in Humility" — Virtual elimination of deaths from the four common communicable diseases of childhood is now in sight. So concluded a study of the reduction of mortality from scarlet fever, whooping cough, diphtheria, and measles. Health people would find more solid satisfaction in their contributions to this happy ending if reductions in scarlet fever deaths were not much greater than those from the two diseases against which they offer prophylactic measures—whooping cough and diphtheria.

ANON. Recent Gains against the Childhood Diseases. Stat. Bull. (Met. Life Ins. Co.) 30, 2:1 (Feb.), 1949.

Hospitalization Has Helped—Infant deaths have dropped to a third of the 1915 rate (100 per 1,000 births in those days). However, the present low rate for the whole country conceals some scandalously high extremes. In 5 states the non-white deaths still exceed the 1915 general rate.

ALTENDERFER, M. E., and CROWTHER, B. Relationship Between Infant Mortality and Socio-Economic Factors in Urban Areas. Pub. Health Rep. 64, 11:331 (Mar. 18), 1949.

On Our Way—We are progressing in our American studies of the efficacy of BCG. In the New York State plan immunization is being extensively used with tuberculin negative reactors who are occupationally exposed — nurses, medical students, hospital personnel.

BIRKHAUG, K. E. New Developments in BCG Vaccination. New York State J. Med. 49, 4:401 (Feb. 15), 1949.

The Order Changeth—You'll have to admit that at least one medical journal opens its pages to the other side of the story. In this one a proponent "presents astutely and temperately certain arguments in favor of compulsory

health insurance." (The quote is from an accompanying editorial.)

BUTLER, A. M. Public Financing of Medical Education, Research, Health and Medical Care. New England J. Med. 240, 9:324 (Mar. 3), 1949.

Hair-Raising Nostrums—Of course you're an authority on scalp health! Aren't you in the health business? My advice to you is to be prepared to keep your friends out of the clutches of the hair experts.

COMMITTEE ON COSMETICS. Hair and Scalp Treatments and Preparations. J.A.M.A. 139, 13:840 (Mar. 26), 1949.

"Count Not the Day Lost——"—Do you know that phorology is the study of disease carriers? I didn't either until this provocative paper drove me to the dictionary. The student of the science who wrote it proposes (posthumously) two useful epidemiological terms.

FORSBECK, F. C. "Infection Unit" and "Index of Aggregation." Pub. Health Rep 64, 11:343 (Mar. 18), 1949.

Never Underestimate the (Will) Power of a Woman—It seems there is more to preparing for babies born without anesthetics than just pep talks. Mothers have to be taught how to do the job. Properly indoctrinated and trained, 9 out of 10 could be—and were glad to be—delivered while awake.

GOODRICH, F. W., JR. Experience with Natural Childbirth. Pub. Health Nurs. 41, 3:122 (Mar.), 1949.

Noses Worse Than Throats—Have you, too, the sort of mind that relishes facts of no likely use to you? Then you'll tuck away happily this finding that when nasal—not throat—carriers of hemolytic streptococci increase then an epidemic is likely to be on its way.

HAMBURGER, M., JR., *et al.* The Significance of Nose to Throat Carrier Ratios in the Epidemiology of Hemolytic Streptococcal Infection. Am. J. Hyg. 49, 2:140 (Mar.), 1949.

Service Plus Research—Because we have no definite measure of mass x-ray as a case finding method, a county-wide survey was undertaken in an attempt to find the answers, some of which cannot be known until time has elapsed to discover new cases among examined and unexamined groups.

COMSTOCK, G. W., *et al.* Tuberculosis Studies in Muscogee County, Georgia. Pub. Health Rep. 64, 9:259 (Mar. 4), 1949.

Trace Elements—References to review articles appearing in formal series have seldom been included in this bibliography but the self-imposed rule is bent this time to permit the mention of an excellent paper. Most of what is known, or maintained, or even guessed about the role of fluorine in dental health is so usefully and clearly set forth that you can't afford to miss it.

MCCLURE, F. J. Fluorine and Other Trace Elements in Nutrition. J.A.M.A. 139, 11:711 (Mar. 12), 1949

First They Bought a Projector—How a visual-aid plan for at-work training of public health nurses grew up into a community health educational film service is provocatively told. The two years' experience has been challenging, alive, and fun, the reporter alleges.

MOORE, W. L. Adventuring with Visual Education. Pub. Health Nurs. 41, 3:134 (Mar.), 1949.

Female of the Species—Among a group of four thousand-odd immunized clerks, reactions to influenza vaccines were not sufficiently numerous nor severe to be a deterrent to future efforts. One finding will give you something to mull over: reactions were twice as common and four times as severe among the "females." Egg-sensitive individuals were excluded, of course.

SADUSK, J. F., JR., *et al.* A Comparative Study of Reactions Following Inoculation with Red Cell Elution and Sharples Centrifuged Influenza Vaccines. Am. J. Hyg. 49, 2:148 (Mar.), 1949.

Go-Getters, Ltd. — An appalled British V.D. Officer writes a "you'll-never-believe-this" sort of account of our amazing case finding antics. Please, please do your best to hunt out this delightfully objective reporting. "We are certainly not ready," he concludes, "if we ever will be, for a venereal disease 'police,' but case-finding . . . might pay dividends."

WILLCOX, R. R. Venereal Disease Case-Finding—the American Way. Pub. Health 62, 5:99 (Feb.), 1949.

Gets Results—Here is an analysis of the relative effectiveness of various case finding procedures in bringing in for treatment 2,400 new cases of syphilis. All this happened in an ordinary control program such as any health department might put on.

WRIGHT, J. J., and SHEPS. C. G. Reports of the North Carolina Syphilis Studies. J. Ven. Dis. Inform. 30, 2:35 (Feb.), 1949.

MOTION PICTURE REVIEWS

For more than a year the Committee on Motion Picture Films of the A.P.H.A. Health Education Section has been studying the problem which health educators and many other health workers continually face in producing and using motion picture films. A recent result of this committee's work was the publication in the February issue of the *Journal* of a bibliography of film catalogs. Reprints of this bibliography are available and it is expected that it will be brought up-to-date from time to time.

The next step in the committee's program is the plan for regular publication in the *Journal* of new film titles with a brief description and reviews of current films which seem to be of outstanding and general interest. The Editorial Board of the *Journal* has approved this recommendation and has set aside space up to a page a month for this purpose. The committee asks that all those who produce new films advise the Association office when these films are ready for release. Information should include running time, whether in color or black and white, whether in sound or silent, width of film, name of producer, intended audience, and terms on which it may be secured and where it may be secured. With this information at hand, the committee will, from time to time, request prints of films which may be reviewed by a team of qualified reviewers. Reviews accepted by the *Journal* for publication will represent the opinions of the reviewers and not necessarily that of the committee or the Association.

The committee expects that reviews will be confined to pictures intended for popular health education or for instruction of various types of public health workers. It does not expect to include medical teaching films, other medical films, or other scientific films primarily designed for professional audiences outside of the public health field. The reviews will deal only with new films as they are produced. Reviews and listings will embrace only those films which have been released since January 1, 1949. Further inquiries concerning the plan for listing and review of films and other aspects of the work of the film committee may be addressed to Mr. Kenneth Widdemer, *Chairman* of the Section Committee on Motion Picture Films, American Public Health Association, 1790 Broadway, New York 19, N. Y.

ASSOCIATION NEWS

SEVENTY-SEVENTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
NEW YORK, N. Y., OCTOBER 24–28, 1949

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1949, the total membership of the Association was 11,102, including 2,093 Fellows, or almost 19 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine, with at least one year of graduate study in public health in a university, Master of Public Health, Diploma in Public Health, or other equivalent degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Applications are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that mem-

bers themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although over 3,000 persons have been duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health*, usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Committee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 13 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depend upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are $12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at $200, covering all future annual dues.

Applications for Fellowship to be considered at the 77th Annual Meeting in New York, N. Y., the week of October 24, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information, address the Membership Department, American Public Health Association.

A.P.H.A. membership application blank on page XXXIX

THE 77TH ANNUAL MEETING

RESERVATIONS WILL BE HELD UNTIL 6:00 P.M. ONLY, UNLESS THE HOTEL IS NOTIFIED OF LATE ARRIVALS

NOMINATIONS FOR THE GOVERNING COUNCIL

The Association Nominating Committee for Governing Council Members reports the following nominations for the Governing Council, in accordance with the new By-laws which call for publication of these names to the Fellowship not less than five months before the Annual Meeting. The Nominating Committee is composed of one Fellow elected by each Section and a Chairman appointed by the Executive Board. The Chairman is George T. Palmer, Dr.P.H., Consultant in Public Health Administration with the California State Department of Public Health, and the other members are: Donald B. Armstrong, M.D., Public Health Education Section; David B. Ast, D.D.S., Dental Health Section; Walter H. Brown, M.D., School Health Section; William H. Cary, Jr., Engineering Section; Halbert L. Dunn, M.D., Statistics Section; Helen F. Dunn, Public Health Nursing Section; Marcia S. Hays, M.D., Maternal and Child Health Section; Ethel A. Martin, Food and Nutrition Section; C. A. Perry, Sc.D., Laboratory Section; Edward A. Piszczek, M.D., Health Officers Section; Dean W. Roberts, M.D., Medical Care Section; James G. Townsend, M.D., Industrial Hygiene Section; and Milton V. Veldee, M.D., Epidemiology Section.

The By-laws further provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than three months before the Annual Meeting." This means that names will be added to the following list if properly supported by petition and received in the Administrative Office not later than July 24.

The change in the election routine which was approved at the Boston Annual Meeting calls for a mail vote on the elective councilors. This is the first time in the history of the Association that all Fellows will have the privilege of voting for Governing Council members regardless of attendance at the Annual Meeting, and it is hoped that every Fellow will exercise this right to vote. Official ballots containing the names of the following nominees and any added by petition will be mailed to all Fellows early in August, and Fellows will be allowed up to September 24 to return their marked ballots. Immediately after this date Tellers appointed by the President will canvass the vote on the elective councilors and will report the result to the Governing Council at its first meeting during the New York City Annual Meeting. The ten nominees receiving the highest number of votes on the ballots cast by the Fellows will be declared elected to fill the three-year terms expiring in 1952.

A MESSAGE FROM THE CIRCULATION DEPARTMENT

Certain 1948 issues of the *American Journal of Public Health* are needed to complete sets for members and subscribers. The *Journals* that are in short supply are January, March, August, September, and October. It will be appreciated if members or subscribers who can spare any of these issues will mail them collect, addressed as follows: Circulation Department, American Public Health Association, 1790 Broadway, New York 19, N. Y.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

POSITIONS AVAILABLE

Public Health Nurse as Director, Metropolitan voluntary nursing agency, staff of *more than 30. Write: Box A-55, Employment* Service, A.P.H.A.

Sanitary Engineer, Maryland State Department of Health. Degree in S.E. with at least six years' sanitary engineering experience, two of which in responsible charge. Starting salary $5,000; five day *week, retirement plan. Write: George L.* Hall, Chief Engineer, 2411 N. Charles St., Baltimore 18, Md.

Sanitary Engineer, city health department near Chicago. Staff includes 7 sanitarians. Salary range $4,000 to $4,800 depending upon training and experience. *Write Box A-56, Employment Service,* A.P.H.A.

Public Health Nursing Supervisor for generalized program in official health agency. Salary range $3,500 to $4,200 depending upon qualifications and training. Community near Chicago; pension, travel expenses; *paid sick leave. Write Box* A-57, Employment Service, A.P.H.A.

Associate Executive Secretary for health council in midwestern city. Graduation from accredited university, advanced study in health field, executive experience in health field required. Experience in *community organization desired. Salary* range $3,500 to $5,400 with annual increment plan. Write Box A-58, Employment Service, A.P.H.A.

Chief Public Health Nurse for City-County Health Department, staff of fifteen nurses. Salary $275–$350 monthly *with possible increase in near future.* Write: Dr. Fred Long, Director of Health, Lincoln-Lancaster County Health Department, 935 R Street, Lincoln, Nebr.

District Health Officer, Thurston-Mason District Health Department, Olympia, Wash. Salary range $7,440–$9,120, plus *8¢ per mile traveling expenses for use of* personal car. Minimum requirements, three years' professional medical experience and the equivalent of one year graduate study in public health. Write: Dr. J. A. Kahl, 1412 Smith Tower, Seattle, Wash.

Assistant Director, State Bureau of Local Health Services. Salary $6,300–$7,900. Write Box A-59, Employment Service, A.P.H.A.

Clinical Laboratory Technician capable of performing laboratory examinations *under the direction of a clinical patholo*gist. Salary range from $150 to $250 monthly depending on qualifications. Write: Dr. George O. Hartman, 20 East Ochoa, Tucson, Ariz.

Medical Technician in approved modern 100 bed general hospital, Southwest Okla*homa, excellent location, 40 hour week,* double pay for holidays, one month paid vacation yearly, paid sick leave, automatic yearly promotions, disability compensation coverage, retirement system. Write Box *139,* Lawton, Okla.

Qualified Public Health Nurses: Greene *County. Official agency; generalized pro*gram. Salary $2,500 plus 8¢ mileage allowance; yearly increment for five years; four weeks vacation; 38 hour week, sick leave, retirement system. State experience and postgraduate study. Write: Ernest Canniff, Chairman, Public Health Committee, Court House, Catskill, N. Y.

Three Qualified Public Health Nurses for Marion County Health Department, Salem, Ore. Salary $250 per month to start; transportation furnished. Permanent. Write: Harold M. Erickson, M.D., State Health Officer, 1022 S. W. 11th Avenue, Portland 5, Ore.

Experienced Bacteriologist for city public health laboratory to perform water and milk laboratory examinations and general bacteriological and serological laboratory work. Salary range $325 to $350 monthly. Write: F. A. Musacchio, M.D., City Health Department, City Hall, Hammond, Ind.

Associate Bacteriologist, public health, Master's degree. Two years postgraduate experience. Salary range $326 to $370 per

month. Permanent position under effective civil service. Write: Director of Laboratories, Laboratory Section, St. Louis Health Division, Room 32, Municipal Courts Bldg., St. Louis, Mo.

Rural Training Center Personnel: Nursing, Sanitation, and other personnel interested in positions in a Rural Training Area apply to: Roland R. Cross, M.D., Director, State Department of Public Health, Springfield, Ill.

Four District Health Officers. Salary $5,760 to $6,960 at present, with probable maximum of $8,000 soon. Write to: Roland R. Cross, M.D., Director, Illinois Department of Public Health, Springfield, Ill.

Dental Hygienist: Assist dentist in dental health program. Work exclusively with children. Salary to start $2,500. Write: Dr. Junius B. Johnson, City-County Health Department, City Hall, Kalamazoo, Mich.

Professor and Chairman of department of Civil Engineering, Eastern University. Recognized specialist in Sanitary Engineering, with teaching and administrative experience preferred. Write: **Box A-60**, Employment Service, A.P.H.A.

Public Health Nurse Supervisor—Minimum requirements: completion of a program of study in public health nursing meeting the requirements of the N.O.P.H.N. and extending throughout at least one academic year, with bachelor's degree preferred. Salary range, $3,340–$3,808; 40 hour week; retirement plan; liberal vacation and sick leave. Write: Personnel Department, City Hall, Jackson, Mich.

ANNOUNCEMENT

Civil Service Commission—County of Wayne

The Civil Service Commission, Detroit, Mich., announces an examination for Public Health Nurses. Applicants must be citizens of the United States. They must have graduated from an accredited school of nursing, must be eligible for registration as nurses in the State of Michigan, and have a certificate in Public Health Nursing or its equivalent. Salary starts at $3,360 with annual increases to $3,720. The Commission will attempt to arrange convenient examination centers for those people who apply. Write to: Civil Service Commission, County of Wayne, 2200 Barlum Tower, Detroit 26, Mich.

POSITIONS WANTED

Public Health Physician, 39, M.D., M.P.H. from leading universities, twelve years full-time public health experience covering both small and large units, five years' teaching experience in medical school, now assistant professor of Public Health and Preventive Medicine. Will consider desirable opening at salary consistent with background. Write **Box Ph-12,** Employment Service, A.P.H.A.

Health Educator, R.N., M.S., female, single, 15 years' college health teaching and considerable experience in administration and organization in nonofficial agencies; experienced public speaker; some creative writing. Interested in position involving administration, organization, education, and creative writing in college or community organization, voluntary or public agency. Write **Box HE-12,** Employment Service, A.P.H.A.

Sanitary Engineer or Public Health Engineer, 37; B.S. in Sanitary Engineering, 14 years' experience (3 with a city Engineering Department; 5 with Sanitary Corps U. S. Army; 6 with a rural health department). Prefer Southern States. Write **Box E-10,** Employment Service, A.P.H.A.

Sanitarian—B.A. in chemistry, male, 27, 2 years' experience in industrial chemistry, veteran (Army CWS), 1½ years' public health experience in environmental sanitation, including milk control and food and drug control. At present employed by state health department of southern state. Desires position as sanitarian with city or county health department in Southern California. Minimum salary: $2,700–$3,000 depending on location. Write **Box S-1,** Employment Service, A.P.H.A.

Public Health Physician, Spanish, with more than 15 years of employment and experience in all problems of public health, including tropical pathology, desires University position (teaching or research) or in public health service (Epidemiology). Write **Box Ph-13,** Employment Service, A.P.H.A.

Opportunities Wanted

Public health administrator; M.D., M.P.H., Harvard; in 1939 reorganized city health department and remained as its director; simultaneously has held important faculty appointment; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Sanitary engineer; B.S., Civil Engineering; several years, sanitary engineer, tropics; past four years, chief, engineering division, county department of health, serving population of 150,000; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Statistician; M.S., Ph.D. degrees; five years' teaching experience; past several years, director, vital statistics, division city health department; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

Health educator; Master's degree, Public Health (Eastern university); four years, health educator, county health department; three years, health coördinator, liberal arts college; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago.

Public health nurse is available for administrative position; graduate of five year public health nursing course; B.S., Simmons; M.P.H. Health education, eastern university; three years, director health education, state university; eight years' executive experience in public health nursing; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

DR. MARTHA ELIOT TAKES WHO POSITION

It was announced in Washington and Geneva on April 16 that Martha M. Eliot, M.D., Associate Chief of the U. S. Children's Bureau, had resigned to accept appointment as Assistant Director General of the World Health Organization, United Nations, in Geneva.

Dr. Eliot, who has served the Children's Bureau for twenty-five years, expected to assume her new position June 1. The appointment was made by Brock Chisholm, M.D., Director General of WHO. Dr. Eliot has been among the group responsible for the original planning of WHO, having been a member of the United States Delegation at the original conference and one of the signers of the original Constitution. In her new position she will be responsible for the Department of Operations, including the supply of experts and demonstration teams and the supervision of fellowships in the program of WHO directed against tuberculosis, malaria, venereal diseases, maternal and child health, etc.

At a press conference Dr. Eliot recalled that in the twenty-five years which she has served the Children's Bureau the infant mortality of the United States had dropped 55 per cent and that maternal mortality had dropped 79 per cent.

Dr. Eliot is immediate Past President of the American Public Health Association and was a recipient in 1948 of a Lasker Award for achievement in public health administration.

DR. LEONA BAUMGARTNER NAMED ASSOCIATE CHIEF OF THE CHILDREN'S BUREAU

On April 16 the appointment of Leona Baumgartner, M.D., Assistant Commissioner of Health of the New York City Department of Health, as Associate Chief of the U. S. Children's Bureau, Washington, succeeding Martha M. Eliot, M.D., resigned, was announced. Dr. Baumgartner's appointment was to be effective June 1 for a period of six months, during which time she will be on leave from New York City, with the possibility that the appointment may be permanent.

Dr. Baumgartner holds the M.D. and Ph.D. degrees from Yale University. She has previously served as District Health Officer and as Director of the Bureau of Child Health of the New York City Department of Health. She is Chairman of the A.P.H.A.'s Association Committee on Child Health and is a member of the Executive Board, A.P.H.A.

NATIONAL HEALTH COUNCIL MEETS

The National Health Council met in 29th annual session at the Hotel Roosevelt in New York City on March 25. Basil O'Connor, President of the American National Red Cross and the National Foundation for Infantile Paralysis, was the main speaker at the luncheon attended by nearly 500 persons. In his subject, "America's Potential for Health," he outlined the great progress that might be made in developing positive health for all the people through the use of local resources and initiative. Said he, "America's potential for health is America's potential for peace."

Other speakers included C. L. Williams, M.D., Assistant to the Surgeon General, who brought greetings from Surgeon General Leonard A. Scheele of the U. S. Public Health Service, and Vlado A. Getting, M.D., Health Commissioner of Massachusetts, in behalf of the Association of State and Territorial Health Officers.

At the business meeting preceding the luncheon the following officers were reëlected:

President, Philip R. Mather
Vice-President, Ernest L. Stebbins, M.D.
Treasurer, Haven Emerson, M.D.
Assistant Treasurer, Franklin M. Foote, M.D.

James E. Perkins, M.D. was elected Secretary.

The business meeting also elected 4 organizations to Council membership—the American Medical Association, the National Foundation for Infantile Paralysis, The American Physical Therapy Association, and the National Multiple Sclerosis Society, the last two as associate members.

The delegates approved revision of the by-laws by permitting broader representation among the membership of national organizations concerned with health.

An increase in the Board of Directors from 31 to 55 was voted. Twenty-one new directors and 8 delegates-at-large were elected.

The recently appointed executive director of the Council, Thomas D. Dublin, M.D., reported 1948 activities and 1949 plans to the delegates and the Board of Directors. "The weakest link in the chain of health services today is the lack of adequately trained professional and technical health personnel in sufficient numbers to meet the need," said he, in recommending increased effort at recruitment and training of public health workers. Dr. Dublin paid tribute to the more than 50 national civic and fraternal as well as health agencies represented in the National Advisory Committee on Local Health Units, which, with their thousands of state and local affiliates, have been working toward the development of adequate local health units and strong community health councils throughout the country.

BOSTON UNIVERSITY HONORS PUBLIC HEALTH LEADERS

The Annual Founders' Day of Boston University, March 14, included honors for Howard A. Rusk, M.D., Professor and Head of the Department of Rehabilitation and Physical Medicine, New York University College of Medicine, and Associate Editor of the *New York Times,* who received an honorary Doctor of Science.

Also to Catherine A. Worthingham, M.A., Director of Professional Education of the National Foundation for Infantile Paralysis, New York, Honorary Doctor of Science, together with Honorary degrees of Doctor of Science in Physical Education to Francisca Reyes Aquino, University of the Philippines, Manila; Ruth Evans, Assistant Supervisor of Health, Physical Education and Safety in the schools of Springfield, Mass.; Anna Hiss, Director of Physical Training for Women at the Univesity of Texas, and William Leonard Hughes, M.D., Professor and Director of Health and Physical Education at Temple University, Philadelphia.

WATER POLLUTION CONTROL ADVISORY BOARD

Another step was taken in the nationwide attack on water pollution with the appointment of government members of the Water Pollution Control Advisory Board. The board now consists of 11 members—6 non-governmental and 5 governmental representatives. The duty of the board as provided by the legislation establishing the board is "to review the policies and programs of the Public Health Service as undertaken under authority of the Act and to make recommendations in reports to the Surgeon General." The recently appointed members of the board are, non-governmental members: Thomas Berrigan, Director and Chief Engineer, Metropolitan District Commission, Boston; L. A. Danse, Chairman, General Motors Industrial Waste Committee, General Motors Corporation, Detroit: Dr. Stanley B. Freeborn, Assistant Dean, College of Agriculture, Univer-

sity of California; Michael Klein, Chief Engineer, Office of the President, Borough of Manhattan, New York City; Carl D. Shoemaker, Conservation Director, National Wildlife Federation, Washington, D. C.; and Nathan T. Veatch, Black & Veatch, Consulting Engineers, Kansas City, Mo. The governmental representatives are: Mark D. Hollis, Assistant Surgeon General and Chief Engineering Officer, U.S.P.H.S., Chairman; Lt. Col. Hugh M. Arnold, C.E., Executive Officer to the Assistant Chief of Engineers for Civil Works; Milton C. James, Assistant Director, Fish and Wildlife Service, Department of the Interior; James W. Follin, Assistant Administrator, FWA; and Ralph R. Will, Administrative Officer, Office of the Secretary, Department of Agriculture.

USE OF COMPOUND 1080

The Service Letter for March 23, 1949, of the National Pest Control Association calls attention to a laxness on the part of many pest control operators in the observance of precautions in the use of compound 1080 in pest control work. Several "case histories" are given to illustrate dangerous practices of some individual operators. Several constructive suggestions are given to reduce accident and fatality hazards in the use of 1080. The New York City Department of Health application for consent by the Commissioner of Health for the use of sodium fluoroacetate (1080) is also reproduced. The National Pest Control Association is located at 3018 Ft. Hamilton Parkway, Brooklyn 19, N. Y.

CUTTER LECTURE BY DR. SPENCE

The Harvard School of Public Health announces that Dr. James C. Spence, Professor of Child Health, University of Durham, England, will deliver the Cutter Lecture on Preventive Medicine on May 11, 1949, at 5 p.m. in Amphitheatre D of the Harvard Medical School. Dr. Spence has chosen as his subject, "Preventive Medicine: the Role of Parents in Child Health." The Cutter Lectures on Preventive Medicine have been held since 1912, according to the terms of the will of Dr. John Clarence Cutter, of the class of 1877, which directed that they should be "free to the medical profession and to the press." In addition, medical and public health students and others interested are cordially invited to attend.

NEW JERSEY REORGANIZATION ADVANCES

Reorganization plans of the New Jersey State Health Department were approved by the State Public Health Council in June, 1948. Steps in carrying out this plan became effective in January, 1949. The Bureau of Laboratories was organized to take over all laboratory functions of the department, hitherto scattered in several divisions or bureaus. The Laboratory Bureau has four sections, bacteriology, chemistry, pathology, and serology. A. J. Casselman, M.D., is the director of the Bureau of Laboratories.

Another bureau organized at that time was the Bureau of Preventable Diseases, comprising sections on alcoholism, communicable diseases (including tuberculosis and venereal diseases), cancer and malignant diseases, dental diseases, and rehabilitation. Carl E. Weigele, M.D., is the director of the reorganized bureau.

BCG VACCINATION FOR INDIAN CHILDREN

The first widespread program of vaccination with BCG (Bacillus Calmette-Guerin) for the prevention of tuberculosis among Indians of the United States will be carried out during April, May, and June by the U. S. Bureau of Indian Affairs. To carry out the program eight vaccination teams were employed and sent to the field beginning on March 15. Each team is composed of one physician, one public health nurse, and a recording clerk. The personnel of the eight teams

convened at Albuquerque, N. M., on March 20 for a ten day instruction period. Included in the group were a doctor and a nurse from Puerto Rico as observers. Technical assistance is provided by the Tuberculosis Control Division of the U. S. Public Health Service, and the vaccine is furnished by the Henry Phipps Institute of Philadelphia.

ENGINEER HALL IN IRAN

In line with President Truman's Inaugural address proposing that the United States give technical assistance to other nations, Lawrence B. Hall, Assistant Chief, Engineering Division, of the Public Health Service's Communicable Disease Center in Atlanta, Ga., left early in March for Iran on a 3 month assignment to help in that country's fight against malaria. From headquarters in Teheran he is supervising training of Iranian personnel in carrying out a DDT spraying program initiated by Justin M. Andrews, M.D., another Public Health Service Officer, following a recent survey.

CONFERENCE ON SMOKE PREVENTION

The Forty-second Annual Conference of the Smoke Prevention Association of America will be held in Birmingham, Ala., May 23 through May 27. The program includes discussions of various types of industrial smoke control problems plus a consideration of the medical aspects of air pollution. The final day of the Conference will be taken up with a visit to the underground gasification of coal experiment, Gorgas, Ala., where the Alabama Power Company will demonstrate features of this experiment. For further information write to D. A. Sullivan, Commonwealth Engineering Company, 72 West Adam Street, Chicago 90, Ill.

TEXAS HEALTH ACTIVITIES APPROVED

The Texas Public Health Association, at its annual meeting in February, 1949, adopted a resolution of commendation for the work of the Texas State Health Department through its staff and under the leadership of the Health Officer, George W. Cox, M.D. Special recognition was given to the addition of the Divisions of Cancer, Health Education, Mental Health, and Hospital Construction to the State Health Department during the past 12 years. Attention was called to the increased activities for the control of venereal diseases, tuberculosis, malaria, typhus, and plague, and the construction of 22 health center buildings and a main office building for the State Health Department during the same period.

In conclusion, the resolution stated:

"Now therefore be it Resolved, that we commend Dr. Cox for his extraordinary achievements; that we endorse his plans; that we give him a vote of confidence; and that we, the public health workers assembled here in convention, pledge our support to the continuation of his activities and policies which mean so much to the successful prosecution of a comprehensive public health program for all the citizens of Texas."

SPREAD OF POLIO BY SEWAGE HAS A COURT TEST

Irving D. Johnson, M.D., Marin County Health Officer, San Rafael, Calif., reports what is believed to be the first court test of an attempt to blame sewage as the direct cause of poliomyelitis.

The patient, a boy of 6 who had contracted polio in May, 1945, was one of 52 cases in Marin County during the epidemic of 1945. In the same year 898 cases occurred in California. The parents of the child attempted to collect $100,000 damages allegedly resulting from sewage in the residence which had overflowed in the basement. Judge Edward Butler presided in the Marin County Superior Court and denied a non-suit motion from the defendant for dismissal, based on lack of evidence and precedence in such cases. The court

gave way to the importance of such a test case and determined that the case should be decided by a jury.

The plaintiff contended that sewage had backed up in his basement on several occasions, in January and February and perhaps April, 1945. The parents claimed to have removed sewage from the basement with shovels, to have scrubbed down the floor with creosote and to have washed the floor with a hose. The child had played with toys in this basement. Among several expert witnesses was Dr. William McD. Hammon of the Hooper Foundation for Medical Research and Professor of Epidemiology at the University of California School of Public Health, who had studied the outbreak and who reached the conclusion that person-to-person spread was the most likely method of infection in this outbreak.

A jury of six men and six women deliberated 1½ hours and rendered a verdict of nine to three in favor of the defendant, the City of Mill Valley. Motion for a new trial was denied.

W. SCOTT JOHNSON

On March 13, 1949, the Association, and more particularly the Engineering Section, lost a strong supporter and friend through the death of W. Scott Johnson. It was almost a quarter of a century ago, 1925, that Mr. Johnson became a member of the Association. In 1933 he was elected a Fellow, and in 1946–1947 he served as Chairman of the Engineering Section Council. His influence was also felt through participation in committee and Section Council activities.

At the time of his death, Mr. Johnson was Chief Engineer and Director, Section of Environmental Sanitation, Missouri Division of Health, a position he had held since 1925. Under his guidance, the section had grown both in size and efficiency to become one of the better divisions of environmental sanitation in the country. His activities extended into other engineering fields, both state and national. The November, 1948, issue of the *Missouri Engineer* paid special tribute to Mr. Johnson upon the completion of 25 years' leadership in public health engineering in Missouri.

SOL PINCUS TO HEAD WHO SECTION ON ENVIRONMENTAL SANITATION

The appointment of Sol Pincus of New York, consulting engineer, as Head of the new Section on Environmental Sanitation for the World Health Organization, Geneva, Switzerland, was announced on April 4. Mr. Pincus left on that date for Geneva. The WHO has made environmental sanitation one of its six top priority programs for 1949.

Mr. Pincus, who is a native of Texas, is a graduate of the Columbia School of Engineering, and has served for two periods with the U. S. Public Health Service, principally in aiding states to develop sanitary engineering divisions. He served from 1935 to 1947 as Deputy Commissioner of the New York City Department of Health, and there directed sanitary engineering and food control activities until he returned to private practice.

LEGISLATIVE PROGRESS IN IDAHO

Public health in Idaho made important steps forward during the recent session of the State Legislature.

One of the foremost objectives of the legislative program of the Idaho Department of Public Health, under the leadership of L. J. Peterson, Administrative Director, was to carry out a proposal considered at the Rocky Mountain Conference on Local Health Units in Salt Lake City last October, which would permit county commissioners acting as county boards of health to make a one mill levy to be used solely and exclusively for local health services. Members of the Idaho delegation

attending this conference, representing varied organizations interested in good health, unanimously endorsed this proposal.

A bill for this purpose was introduced by the Public Health Committee of the House of Representatives and in passing both the House and the Senate received 95 favorable votes out of 103. It was signed by Idaho's governor in March.

Previously, the one mill proposal had been endorsed by the State Association of County Commissioners and Clerks, the Medical Association, the Dental Association, Anti-Tuberculosis Association, Congress of Parent-Teachers, the Junior Chamber of Commerce, Farm Bureau, Home Economics Association, the Idaho Division of the American Cancer Society, and other organizations interested in good health.

A second proposal endorsed at the Salt Lake City conference calling for an equalization fund for local health departments was not presented to the Legislature, principally because of federal legislation pending in Congress. It must be pointed out that the one mill levy will raise an estimated $500,000, approximately $1 per capita.

Other legislative achievements in which the Department of Public Health was interested include:

Approval of a uniform law on vital statistics; modernization of sanitation laws covering all types of eating and drinking establishments; reactivation of the public health industrial hygiene program; permission for counties, municipalities, and cities to vote on revenue bonds for construction of water and sewage treatment plants; additional powers in the protection of public water supplies. A bill requesting a state appropriation for financing a mobile x-ray unit was introduced but not passed.

Assistance was also given to the State Medical and Dental Associations in the approval of modern medical and dental practice acts. The dental act permits licensing of dental hygienists.

ACTING ON A REPORT

The six national nursing organizations have a joint committee on implementing the Brown report (*Nursing for the Future,* Esther Lucille Brown, Ph.D.). Its program is "to analyze and to plan toward the solution of major nursing service problems and to initiate action to meet present needs as well as long-range goals." It has distributed to the nation's nurses a study guide for use by local groups in analyzing community nursing needs and ways of meeting them.

The Chairman of the committee is Mary C. Connor, Research Associate of Teacher's College Division of Nursing Education at Columbia University. An executive committee of 7 members includes:

Ella Best, Executive Director, American Nurses' Association
Gladys Dondora, American Association of Industrial Nurses
Anna Fillmore, National Organization for Public Health Nursing
Adelaide A. Mayo, National League of Nursing Education
Mary M. Roberts, *American Journal of Nursing*
Alma Vessells, National Association of Colored Graduate Nurses
Dorothy Williams, Association of Collegiate Schools of Nursing

The Executive Secretary is Helen C. Goodale, and the headquarters office is at 250 W. 57th St., New York 19.

A subcommittee on School Data Analysis, under the chairmanship of Louise Knapp, director of the Washington University School of Nursing in St. Louis, is surveying nursing education resources. The results of a questionnaire study of nursing schools will be available in mid-summer. It is expected to furnish a base upon which "an efficient system of preparing nurses to meet the nation's nursing needs" can be planned.

MENTAL HYGIENE DIVISION IN A LOCAL HEALTH DEPARTMENT

Westchester County (N. Y.) is the only county in the state with a mental hygiene division in its health department. Serving a population of more than 300,000, the division has three clinics in different parts of the county. In 1948, a total of 1,900 interviews were held by these clinic staffs, doubling the demand of the previous year. The Health Commissioner, William A. Holla, M.D., reports that the entire department is becoming psychiatric-conscious. Through lectures and conference the bedside nurses and other workers are becoming aware of the mental health implications of their activities.

The division was first organized in 1946 to serve veterans, but children currently constitute 50 per cent of the case load, and the adults are both veterans and non-veterans.

The director of the division is Avraam T. Kazan, M.D. Its 1948 budget of nearly $65,000 was shared equally by the county and the state.

AMERICAN HEART ASSOCIATION BOARD APPROVES LOCAL HEALTH UNITS RESOLUTION

At a meeting on March 8, 1949, the Board of Directors of the American Heart Association approved the following resolution on local health units:

"The Board of Directors of the American Heart Association is keenly aware of the necessity for complete coverage of the Nation with full-time local health departments so staffed and financed that they may render the basic public health services commonly accepted as the right of all citizens. With knowledge of the present deficiencies in the quantity, quality and distribution of such services the Board urges its membership and its affiliate bodies to initiate and give active support to all appropriate measures that will obtain for their communities competent health departments.

"The Board further recognizes the need for financial assistance to many local communities for providing the services and facilities they require and so, to assure a strong nation-wide public health structure, approves in principle federal legislation designed to make such financial assistance available.

The American Heart Association is in full accord with the program of the National Health Council and its National Advisory Committee on Local Health Units for joining together, in coöperative action, the professional and lay forces to gain the desirable objective of adequate full-time local health services for all our people."

MEDICAL SERVICE CORPS APPOINTEES

When the Medical Service Corps was organized in 1947, 4 sections of the corps were established. The chiefs of 3 of these sections were appointed recently in ceremonies held at the Office of the Surgeon General, U. S. Army, in Washington. The recently appointed sections chiefs were: Lt. Col. Charles S. Gersoni, Medical Allied Sciences Section; Major Raymond J. Karpen, Sanitary Engineering Section; and Major John V. Painter, Pharmacy, Administration and Supply Section.

The present Medical Service Corps has approximately 750 officers, of which 640 are in the Pharmacy, Administration and Supply Section, 98 in the Medical Allied Sciences Section, 16 in the Sanitary Engineering Section, and 1 in the Optometry Section.

BRUCE MEMORIAL AWARD TO DR. BAYNE-JONES

The American College of Physicians at its meeting in New York late in March awarded the Bruce Memorial Award to Dr. Stanhope Bayne-Jones, the President of the joint administrative board of the New York Hospital-Cornell Medical Center, New York City, "for outstanding achievement in preventive medicine."

The James D. Bruce Memorial Medal was presented by Dr. Walter W. Palmer, President of the College, at its annual convocation. The citation described Dr. Bayne-Jones as "an inspiring teacher" at Johns Hopkins University, the University of Rochester, and

Yale University, where he had an important part in shaping the careers of many young physicians. Dr. Bayne-Jones during World War II was a Brigadier General in the Army Medical Corps and was Deputy Chief of the Preventive Medicine Service in the Office of the Surgeon General.

CORRECTION — DR. HUGH S. CUMMING A GRADUATE OF THE UNIVERSITY OF VIRGINIA MEDICAL SCHOOL

The editorial in the February issue of this *Journal*, page 225, stated that the late Dr. Hugh S. Cumming had graduated from the University College of Medicine at Richmond.

It now appears that, like other medical graduates in the 1890's, Dr. Cumming graduated from two medical schools. It appears that he first graduated from the University of Virginia Medical School at Charlottesville, and later received the second M.D. degree from the University College of Medicine at Richmond. The University of Virginia very naturally claims Dr. Cumming as an alumnus.

CONFERENCE OF PROFESSORS OF PREVENTIVE MEDICINE

Leland W. Parr, Ph.D., Chairman of the 1949 Conference of Professors of Preventive Medicine, has announced that the conference will meet on Monday, October 24, in New York City at the time of the 77th Annual Meeting of the American Public Health Association. The conference was organized in 1942 in St. Louis at the meeting of the A.P.H.A. that year. Its purpose is to promote fuller acquaintanceship among the men and women, part- or full-time teachers of hygiene, preventive medicine, and public health in the medical schools of the United States and Canada.

Dr. Parr, who is Professor at the George Washington University School of Medicine, Washington, and the Secretary, who is David D. Rutstein, M.D., 25 Shattuck Street, Boston, will welcome suggestions regarding the 1949 program.

ACADEMY OF PEDIATRICS REPORTS ON STUDY AND PROGRAM

The findings of a three year study of child care and plans of a nation-wide program for improvement of child health were announced by the American Academy of Pediatrics' president, Warren R. Sisson, M.D., of Boston, at a meeting in New York on April 2. Terming the study the most comprehensive inventory of the nation's health services ever undertaken by any organization, Dr. Sisson said that factual information collected from each of the 3,000 counties of the United States will enable health planners to know the individual needs of local communities.

"The program of the Academy at national and state levels is based on recommendations of the doctors themselves and will continue to call for coöperative effort on the part of practising physicians, health officials and individuals, nationally and in even the smallest communities. It is designed to put modern techniques and facilities more conveniently at the disposal of the physician, particularly the general practitioner." The family doctor, far from becoming extinct, according to the findings, is the bulwark of child care in this country. Two-thirds of the 116,000 practising physicians in the United States are general practitioners.

Although America's medical care of its children is among the best in the world, and the health level is the best in history, serious gaps and deficiencies exist; 3 babies died for every 2 soldiers killed in action during a year of World War II. In some countries where modern medical services are scarce, 5 times as many infants die as in more favored communities. While infant mortality's national average stands the lowest in history, there is variation from county to county and from state to state. In

one state it is as high as the national average was a quarter-century ago. The geography of health follows closely the geography of medical services.

The Academy's program proposes to utilize university medical centers as hubs from which would be "beamed" post-graduate teaching and metropolitan medical services directly into communities isolated from specialist care, clinic care and the highly skilled diagnostic and treatment services found in the cities. In this sense 2,000 of the 3,000 counties of the nation are isolated.

Individual state reports and recommendations are being published. State councils and committees representative of medical, health and lay groups are being created and stimulated to provide increased public health services and programs to combat the heavy toll of premature births and rheumatic fever.

Winthrop Rockefeller, Chairman of the Board of Trustees of New York University-Bellevue Medical Center; Dr. Thomas Parran, Dean of the new Graduate School of Public Health of the University of Pittsburgh; and Dr. R. L. Sensenich, President of the American Medical Association, as guest speakers praised the Academy for its decision to carry out its own recommendations based on the findings; for the constructive and non-controversial planning for the overall improvement of child health and for the unique move whereby the doctors requested and received the active coöperation of the Public Health Service and the Children's Bureau in the conduct of the study.

NEW MEXICO PUBLIC HEALTH ASSOCIATION

The 21st Annual Meeting of this A.P.H.A. Affiliated Society in New Mexico was held at Roswell, March 23 to 26, and the following officers were elected to serve for the forthcoming year. The offices of Librarian and Delegate to the United States-Mexico Border Public Health Association are newly created.

President—H. D. Newman, M.D.
President-elect—Myrtle Greenfield
Vice-President—Jean Prager
Librarian—Helen M. Boss
Representative on A.P.H.A. Governing Council—Billy Tober
Delegate to Western Branch, A.P.H.A.—Mary Pollard
Delegate to U. S.-Mexico Border Public Health Assn.—Eunice Vandervoort
Secretary-Treasurer—Mary M. Gilliland

TEXAS PUBLIC HEALTH ASSOCIATION

The Texas Public Health Association held its 1949 Annual Meeting in San Antonio from February 20 to 23. The registered attendance was over 500. New officers were elected as follows:

President—William R. Ross, M.D.
President-elect—Barnie Young
1st Vice-President—Graham Smoot
2nd Vice-President—Elvira Oetken
Executive Secretary—Earle W. Sudderth

PUERTO RICO PUBLIC HEALTH ASSOCIATION

The Eighth Annual Meeting of the Puerto Rico Public Health Association was held February 9–12 at the School of Tropical Medicine in San Juan. The registration was larger than at previous meetings and all sessions were well attended. The new officers of this society are as follows:

President—Juan A. Pons, M.D.
President-elect—Manuel A. Perez
Vice-President—Emilia Figueroa
Treasurer—Olga Martinez
Secretary—Raefael Pirazzi
Sub-secretary—Carmen Acevedo
Representative on the Governing Council, A.P.H.A.—Guillermo Arbona, M.D.

Among special guests from outside the Island were Herman E. Hilleboe, M.D., Commissioner of Health of New York State; John B. Hozier, M.D., Senior Surgeon, U. S. Public Health Service, New Orleans; Andrew J. Krog of New York; Edward G. McGavran, M.D., Dean of the School of Public Health, University of North Carolina; William

McKee Germain, M.D., Professor of Pathology, University of Cincinnati; John S. Moorhead, M.D., Commissioner of Health of the Virgin Islands; Glenn S. Usher, M.D., Venereal Disease Consultant, U. S. Public Health Service, New Orleans.

HEALTH EDUCATION WORKSHOPS

Following is a summary of announcements of a number of health education seminars or workshops being held during the summer of 1949. No attempt has been made to secure complete information on such courses. Information is presented about those whose material has come to the offices of the Association without solicitation:

Arizona—Arizona State College, Tempe, June 20–30—Second annual health educational workshop for school administrators and supervisors, 2 points credit. Cosponsors are the Arizona State Health Department and the U. S. Children's Bureau, with the Arizona and American Medical Associations as coöperating agencies. Consultants to be present for the workshop are:

T. H. Butterworth, U. S. Public Health Service
Donald Dukelow, M.D., American Medical Association
Charlotte Leach, National Tuberculosis Association
John L. Miller, Superintendent of Schools, Great Neck, N. Y.

The director of the workshop is Frank R. Williams, Director of Health Education, Arizona State Health Department, Phoenix. Presumably information on fees, housing, etc., are available from him.

Connecticut—Yale University—Department of Education, Graduate School in coöperation with the University Department of Public Health—and several official and voluntary agencies including the State Health Department, June 27–August 5 plus 2 weeks for the preparation of term papers and reports on projects. Graduate seminar in health education designed to meet the needs of both elementary and secondary school teachers. Workshop techniques will be used enabling each student to give special attention to his particular problems.

Represents 8 points of credit.

Tuition is $120. Some scholarships are available for Connecticut personnel. Candidates for an advanced degree at Yale will need to meet the usual University admission requirements; those not degree candidates need only to include with their applications a one page summary of their particular problems and a letter of recommendation from school principal or superintendent outlining their present or contemplated health education responsibilities.

Applications should be sent to Clyde M. Hill, Chairman, Department of Education, Yale University, New Haven. Scholarship applications to Scholarship Committee, Connecticut Tuberculosis Association, 43 Farmington Avenue, Hartford, Conn.

Massachusetts — Harvard University School of Public Health, Boston, July 11–23. Workshop in Nutrition Education, to acquaint persons in different areas of the United States with research programs and nutrition education for public schools; financed by grants from the Nutrition Foundation, Inc., and Swift and Co. Limited to 20 to 25 persons selected from those responsible for the health and education programs in their own schools. The same group will be brought back for purposes of evaluation in 1950. Transportation and expenses are on a scholarship basis. Apply Elizabeth Lockwood, Ph.D., Department of Nutrition, 695 Huntington Avenue, Boston 15.

New York—New York University, New York City, 3rd Annual Health Education Institute: School and Community Problems in Tuberculosis Education. August 15–September 9. Credit 2 to 6 points. Tuition $15.50 per point.

Registration $3.00. Apply Dr. Morey R. Fields, Department of Health and Physical Education, New York University, Washington Square.

New York—Syracuse University, Syracuse, July 5–23. Health education workshop for those responsible for or contributing to the secondary school health program. Credits 3 points, Tuition $51.

August 15–27, with the coöperation of the New York State Committee on Tuberculosis and Public Health, Institute for Tuberculosis Workers, Credit 2 points. Limited number of out-of-state workers accepted. Apply John Shaw, Chairman, Division of Teacher Education, Syracuse University, Syracuse, N. Y.

Ohio—University of Cincinnati, three consecutive Health Education Institutes:

Health Education—June 21–June 26
Social Hygiene—June 28–July 2
Mental Hygiene—July 5–July 10.

Fees: Per credit hour

Resident—Undergradute $7.50; Graduate $10.00
Non-resident — Undergraduate $9.00; Graduate $11.00

Some scholarships are available. Apply Dr. J. R. Heller, Medical Director, Division of Venereal Diseases, U. S. Public Health Service, Washington, D. C. For other details apply Dean, Summer School, University of Cincinnati, Cincinnati, 20.

Oklahoma — University of Oklahoma, Norman, June 20–July 28 in coöperation with State Departments of Education and Health. Workshop to develop materials for a curriculum in health education for elementary schools. Enrollment limited to 25 or 30. Inquire Dr. Laurence T. Rogers, Faculty Exchange, University of Oklahoma, Norman.

Pennsylvania—University of Pennsylvania, Philadelphia, June 27 to July 29, Institute of Health & Human Relations. Joint sponsorship of U. S. Public Health Service, American Social Hygiene Association and Pennsylvania State Health Department. Five semester credit hours and tuition $110. Registration limited to 50 students. Dr. J. H. Stokes, Director, Institute for the Study of Venereal Disease, University of Pennsylvania Hospital, 36th and Spruce Streets, Philadelphia 4. For scholarships apply Dr. Heller as above.

Rhode Island—Rhode Island State College, Kingston. Courses on Education for Family Life, July 5–August 12. Tuition $8.00 per credit hour; $10.00 non-residents. Apply Director of Summer School, Rhode Island State College, Kingston

Washington—University of Washington, Seattle, June 20–July 20. Sponsored jointly by the Department of Public Health and Preventive Medicine of the Medical School, the College of Education, School of Nursing Education, and the Department of Health and Physical Education. Two courses directed by Dr. Dorothy Nyswander of the University of California School of Public Health as follows:

1. *Health Education*—designed for classroom teachers, special teachers of health subjects, public health nurses, and school administrators.
2. *Public Health Program*—planned for school administrators and school health coördinators. Deals with the place of the health program in the total school program, administrative problems of the school health program, and the relationship of the school health program to the whole community health program.

The two courses follow each other from 8 to 10 in the morning, Monday to Friday. Each carries 2½ hours of credit in education.

For details as to tuition, housing arrangements, entrance requirements, etc., inquire University of Washington Summer School, Seattle.

RECENT ALCOHOL RESEARCH EVENTS

Two changes in organizations dealing with the problem of alcoholism took place early in the current year. At a special meeting in January the membership of the Research Council on Problems of Alcohol voted to transfer its research operations and assets to the National Research Council and its public informational and educational publications to the Division of Mental Hygiene of the U. S. Public Health Service. In commenting on this decision the President, A. J. Carlson, M.D., said, "The decision of these two national agencies to concern themselves with the problems of alcohol is a clearcut reflection of the progress made in this field over the past decade."

For the past 11 years the Council on Problems of Alcohol has furnished leadership in developing state and local medical care programs for alcoholics. It has stimulated research on the causes and treatment of problem drinkers. It is at present supporting a 5 year research and treatment project on alcoholism at the Cornell-New York Hospital Medical Center in New York; a study of the biochemical factors in problem drinking, at the University of Texas Biochemical Institute; a study of the endocrinological factors at the New York University-Bellevue Hospital Medical Center; a study of allergic factors at the University of Washington Medical School; and a treatment project planned for the School of Medicine of either the University of Chicago or University of Illinois. These projects are now under the supervision of the National Research Council, and its Chairman of the Division of Medical Sciences, is Lewis H. Weed, M.D.

In this transfer of assets the New York Office of the Research Council on Problems of Alcohol was closed. The former director, Joseph Hirsh, is now a member of the Medical Advisory Commission, Division of Alcohol Studies and Rehabilitation, Virginia State Health Department.

At about the same time an Organization Committee for Research on Medical Treatment of Alcoholic Patients was formed. Its purpose is to explore fully the toxic properties and therapeutic value of a drug known as tetraethyl thiuram disulfide. Used in the vulcanization of rubber, there have been reported instances of its creating an intolerance for alcohol, and has been used in the treatment of alcoholics in Denmark and Sweden. The new committee will carry forward research begun by H. Brieger, M.D., Assistant Professor of Preventive Medicine, Jefferson Medical College, whose report indicates the need for further investigation before the drug can be considered safe for the treatment of alcoholics.

The Chairman of the Organization Committee is Edwin G. Zabriskie, M.D., Professor Emeritus of Clinical Neurology, Columbia University College of Physicians and Surgeons. His six associates are all New York physicians. The committee is trying to raise $50,000 and will begin its research as soon as $25,000 is available. Temporary offices are at 143 East 39th St., New York City, and the Acting Executive Secretary is Basil G. Eaves.

PERSONALS

VIRGINIA ARNOLD, Nurse Officer, Office of International Health Relations, U. S. Public Health Service, attended the 3rd session of the United Nations Commission on the Status of Women, at Beirut, Lebanon. March 21–April 8, as adviser to the United States delegation on health, education, and nursing.

JOHN A. BARGER, M.D.,† formerly with the Bureau of Preventable Diseases, Florida State Board of Health has been appointed Assistant Director of Public Health, Norfolk, Va.

CHARLES P. BERGTHOLDT. M.P.H.,†

formerly Assistant Director of the Division of Industrial Hygiene, Nebraska State Department of Health, Lincoln, became Industrial Hygienist at the U. S. Naval Gun Factory, November 1, 1948, with headquarters in the Medical Department of the U. S. Naval Gun Factory, Washington 25, D. C.

GEORGE F. CAMPANA, M.D.,* most recently a District Health Officer of the Massachusetts Department of Public Health, became Health Officer of Milford, Conn., on March 1.

FILIBERTO RAMIREZ CORRIA, who since 1933 has been pathologist at the Finlay Institute in Havana, Cuba, has been appointed Director General of the Finlay Institute effective January 21.

MARY E. CHAYER, R.N.,* has been promoted to a full professorship in nursing education at Teachers College, Columbia University, New York City, effective July 1.

JAMES GORDON CUMMING, M.D., Dr. P.H.,† has retired, effective March 1, as Director of the Bureau of Preventable Diseases of the District of Columbia Health Department after 24 years of service. Dr. Cumming's career includes the directorship of the Pasteur Institute, University of Michigan; directorship of the Bureau of Communicable Diseases, California State Department of Health; Health Officer of Philadelphia, Pa., and long service in the Armed Forces.

DONALD G. EVANS, M.D.,* formerly Director of the Washington State Department of Public Health and now in private practice, is the new president of the King County (Washington) Anti-Tuberculosis League.

HAROLD B. GOTAAS, Sc.D.,* Professor of Sanitary Engineering, University of California, Berkeley, since 1946, was recently appointed Chairman of the Division of Civil Engineering. During the recent war he was assigned by the Army to the Institute of Inter American Affairs as Director of Health and Sanitation and later as President.

FREDERICK O. GRAEBER, M.D., M.P.H., has been appointed the first full-time Malheur County, Oregon, Health Officer with headquarters in Vale.

RALPH GREGG, M.D., who first joined the Service in 1928, has been made Assistant Chief of the Foreign Quarantine Division of the U. S. Public Health Service. Dr. Gregg served abroad with the Foreign Quarantine Division at American Consulates in Poland, Italy, Ireland, and England, in charge of medical examination of aliens. He succeeds FREDERICK W. KRATZ, M.D., who has been assigned to the Public Health Service Office, Region 3 in Washington, D. C., as Program Director, Hospital Facilities Division.

SIDNEY V. HAAS, M.D., was recently honored with a Golden Book of World Tributes and a luncheon at the New York Academy of Medicine for his contribution to pediatrics, with particular reference to his original and pioneering work in celiac disease and in the treatment of hypertonic infants.

MARGUERITE F. HALL, Ph.D.,* formerly Associate Professor of Public Health Statistics, University of Michigan, has been appointed to direct the Bureau of Vital Statistics and Administration in the New Jersey State Department of Health.

BERNARDO A. HOUSSAY, M.D., of Argentina, co-winner of the 1947 Nobel Prize for physiology and medicine, is in the United States as a Special Research Fellow of the Public Health Service to do research for 3 months at the National Institutes of Health in Bethesda, Md.

JULIA JANE HEREFORD,† Associate Pro-

† Member A.P.H.A.

fessor of Nursing, has been appointed to serve as Associate Dean of the School of Nursing at Vanderbilt University, Nashville, Tenn., until July 1, when she will become Dean on retirement of Frances Helen Zeigler.

KENNETH D. JOHNSON, General Counsel of the National Security Resources Board, has been appointed Dean of the New York School of Social Work succeeding WALTER W. PETTIT, who retired.

CAROLYN E. KINNEY has been appointed as Nurse Consultant in Mental Hygiene, Kansas State Board of Health, coming to her new position on completion of the 16 month course for Mental Hygiene Nurse Consultants at Teachers College, Columbia University.

BETTY MALINKA,† Indiana Field Representative of the National Foundation for Infantile Paralysis and two term member of the Indiana Legislature, recently won the 1948 Oberlin Award of the Lake County (Indiana) Medical Society for obtaining "more and better health legislation in the 1947 legislature than in any previous session."

LAD R. MEZERA, M.D.,† recently Assistant Director of the Maricopa County (Arizona) Health Unit, is now Acting Director of Maternal and Child Health, Arizona State Health Department.

ELEANOR L. MCKNIGHT, M.S.,† has been appointed Chief of the Division of Nutrition, Bureau of Food Control, Baltimore Department of Health.

PABLO MORALES-OTERO, M.D.,* Director of Puerto Rico's School of Tropical Medicine, has been appointed to a chair on the Medical Faculty of Columbia University in New York.

JAMES J. QUINLIVAN, M.D.,† has received permanent appointment as Assistant Director of Local Health Administration in the New York State Health Department's Division of Local Health Services. He served as acting Assistant Director from March, 1948.

WILLARD C. RAPPLEYE, M.D.,† who has been Dean of Columbia University College of Physicians and Surgeons, New York City, and of related schools, has been appointed Vice-President of Columbia University in charge of medical affairs.

DAVID RESNICK,* New York Public Relations Counsellor, has been retained as Consultant to the American Hearing Society of Washington, D. C.

BROOKS RYDER, M.D.,† formerly District Health Officer, Quincy office, Massachusetts Department of Public Health, has joined the Bingham Associates Fund in Boston to carry on the medical extension work of Tufts Medical School and the Joseph H. Pratt Diagnostic Hospital.

CLAUDE A. SELBY, M.D.,† formerly Public Health Consultant with the War Assets Administration, has been appointed to the directorship of the Cameron County (Texas) Health Unit.

GEORGE A. SILVER, M.D., M.P.H.,† was recently appointed Health Officer of the Eastern Health District in Baltimore, succeeding HARRY L. CHANT, M.D., M.P.H., who has become Director of the Medical Care Clinic of Johns Hopkins Hospital, Baltimore.

EDWARD B. SINCLAIR, M.D., has been appointed crippled children physician, Connecticut State Department of Health. After discharge from the army in 1946, Dr. Sinclair was Medical Consultant for Vocational Rehabilitation, Veterans Administration office, Providence.

ALBERT SZENT-GYORGYI, M.D., Professor of Biochemistry, University of Budapest, and 1937 Nobel prize winner in Medicine for discoveries result-

ing in the isolation and identification of vitamin C, and for his fundamental work on biological oxidation, is working as a Special Research Fellow at the National Institutes of Health, Bethesda, Md.

MATTHEW TABACK, M.A.,† has been appointed first Director of the Bureau of Biostatistics in the Statistical Section, Baltimore Health Department. The Statistical Section is under the direction of W. THURBER FALES, D.Sc.*

PAUL W. THURSTON has been appointed Director of Community Case Finding for the Queensboro Tuberculosis and Health Association, New York.

L. O. TUCKER is the new advisory milk sanitarian for the Washington State Health Department succeeding JOHN B. Drake, who has resigned to teach in the Division of Public Health and Preventive Medicine of the University of Washington Medical School.

VIRGINIA STATE HEALTH DEPARTMENT—PERSONNEL CHANGES

FRED C. HEATH, M.D.,† Health Officer of the Giles-Montgomery-Radford Health District, and

MILDRED ESTHER SCOTT, M.D.,† Health Officer of the Rockingham-Harrisonburg Health Department are studying at Johns Hopkins School of Hygiene and Public Health.

GEORGE E. WATERS, M.D., was appointed Health Officer of the Rockingham-Harrisonburg Health Department effective January, 1949.

J. A. FIELDS, M.D., resigned as Health Officer of the Halifax Health District, as of November, 1948.

R. M. WILSON, M.D., became Health Officer of the Henrico County Health Department in December, 1948.

J. C. ELLINGTON, M.D.,* recently assumed his duties as Health Officer of the City of Lynchburg.

J. E. SMITH, veteran of World War II, has been appointed sanitarian for the County of Chesterfield.

ROBERT M. BEATTIE, who served in the United States Navy during World War II, has been appointed sanitarian of Nottoway County.

E. E. RENN, formerly with the malaria control project in Norfolk, has been made sanitarian of Warwick county.

EDWIN H. WEST, M.D., on February 15, became Assistant Director of Tucson-Pima (Arizona) Health Unit succeeding C. R. KROEGER, M.D.,† who resigned to become Health Officer of Imperial County, California.

WEST VIRGINIA—PERSONNEL CHANGES:

ISABELL DOROTHY TAYLOR has been appointed Medical Social Consultant in Maternal and Child Health, State Department of Health.

PAUL D. BIBB is now Hospital Field Representative of the State Department of Health, succeeding A. J. WILLIAMSON who resigned to become Administrator of the Grafton City Hospital.

BERTHOLD ZOFFER,† Senior Assistant Surgeon, has been loaned to West Virginia by the U. S. Public Health Service as Medical Officer in charge of the West Virginia Medical Center in South Charleston.

Deaths

ANNA M. GOVE, M.D.,† Physician and Professor Department of Health, Woman's College University of North Carolina, Greensboro. (Unaffiliated.)

EDGAR M. GRIFFITH, M.D.,† Health Officer Cass County Health Unit, Harrisonville Mo. (Health Officers Section.)

ROY W. MORRISON, Ph.D.,† University of Florida, College of Education, Gainesville. (Public Health Education Section.)

CONFERENCES AND DATES

American Association of Social Workers. Cleveland, Ohio. June 10–12.

American Physical Therapy Association. Copley Plaza Hotel, Boston, Mass. June 19–24.

American Public Health Association—77th Annual Meeting, New York, N. Y. October 24–28.

American Society of Medical Technologists. Hotel Roanoke, Roanoke, Va. June 20–23.

American Water Works Association:
Annual Conference. Stevens Hotel, Chicago, Ill. May 30–June 3.
New Jersey Section Outing. June 23.
Pacific Northwest Section May 12–14.

Arizona Public Health Association. Hassayampa Hotel. Prescott, Ariz. May 12–13.

Association for Physical and Mental Rehabilitation. Third Annual Convention. Hotel New Yorker, New York, N. Y. May 18–21.

Canadian Public Health Association. 37th Annual Meeting. Halifax. June 28–30.

Colorado Public Health Association. Vail Hotel, Pueblo, Colo. May 23–24.

Commonwealth and Empire Health and Tuberculosis Conference. Central Hall, London, England. July 5–8.

Connecticut Public Health Association. Hartford, Conn. June 14.

First Congress International Hospital Association. Amsterdam and Groningen, Holland. May 30–June 4.

Florida Public Health Association. George Washington Hotel. West Palm Beach, Fla. October 6–8.

Georgia Public Health Association. DeSoto Hotel, Savannah, Ga. May 2–4.

Health Officers and Public Health Nurses of New York State. Lake Placid, N. Y. June 20–23.

Idaho Public Health Association. Legion Hall, Twin Falls, Ida. May 23–24.

International Association of Milk and Food Sanitarians. Deschler-Wallick Hotel, Columbus, Ohio. October 20–22.

International Congress on Rheumatic Diseases. New York, N. Y. May 30–June 3.

Iowa Public Health Association. Des Moines, Iowa. June 2–3.

Massachusetts Public Health Association. Amherst, Mass. June 15–17.

Michigan Public Health Association. Hotel Statler. Detroit, Mich. November 9–11.

Middle States Region Health Educator Conference. Milwaukee, Wis. May 11–13.

Minnesota Public Health Conference. Nicollet Hotel. Minneapolis, Minn. September 30.

Missouri Public Health Association. Jefferson City, Mo. May 4–6.

National Association of Sanitarians. Biltmore Hotel, Los Angeles, Calif. August 15–18.

National Conference of Social Work. Cleveland, Ohio. June 12–18.

National Convention of the American Red Cross. Atlantic City, N. J. June 27–30.

National Education Association. Hotel Statler, Boston, Mass. July 4–8.

National Social Welfare Assembly. New York, N. Y. May 18.

Royal Sanitary Institute. Brighton, England. May 23–27.

Society of American Bacteriologists. Cincinnati, Ohio. Hotel Netherland Plaza. May 16–20.

South Carolina Public Health Association. Gloria Theater. Myrtle Beach, S. C. May 30–June 1.

Third Inter-American Congress of Radiology. Santiago, Chile. November 11–17.

Washington State Public Health Association Spokane, Wash. September 19–20.

Western Branch American Public Health Association. Biltmore Hotel, Los Angeles, Calif. May 30–June 1.

West Virginia Public Health Association. Daniel Boone Hotel, Charleston, W. Va. June 2–3.

facts concerning

Pen-Aqua

a new and highly practical penicillin formulation for aqueous injection at 24-hour intervals.

What it is—PEN-AQUA provides Procaine Penicillin G and buffered Potassium Penicillin G in combination for constituting an aqueous solution-suspension for intramuscular injection.

What it does—The soluble Potassium Penicillin is absorbed within an hour following injection, thus providing a correspondingly high initial blood concentration of penicillin to overwhelm invading bacteria at the outset.

The relatively insoluble Procaine Penicillin is absorbed slowly, thus providing a repository effect which sustains therapeutic penicillin blood levels for 24 hours or more in the majority of patients.

How to use it—PEN-AQUA is quickly prepared for use by introducing the directed quantity of Water for Injection, USP, or Isotonic Solution of Sodium Chloride, USP, directly into the sterile PEN-AQUA vial, with thorough shaking before the withdrawal of each dose. So constituted, each cc. contains 300,000 units of Procaine Penicillin G per cc., plus 100,000 units of Potassium Penicillin G per cc., in uniform suspension which passes through the needle freely. PEN-AQUA is absorbed completely, without nodule or cyst formation.

When to use it—PEN-AQUA may be used in all conditions amenable to systemic penicillin therapy, in cc. doses corresponding in frequency with that employed with Penicillin in Oil and Wax (Romansky Formula)—generally, one cc. each 24 hours, 12 hours in certain severe or refractory infections. PEN-AQUA is intended for intramuscular use only. Suspensions retain their potency for one week under refrigeration. In the dry state, PEN-AQUA retains full potency for a year.

How supplied—PEN-AQUA is available in *multiple-dose vials* containing 1,500,000 units of Procaine Penicillin G, plus 500,000 units of buffered Potassium Penicillin G, with space provided for the introduction of 4.5 cc. of diluent; also in *single-dose vials* containing 300,000 units and 100,000 units of Procaine and Potassium Penicillins G, respectively, with space provided for the introduction of 1 cc. of diluent.

DOES YOUR CITY
KNOW ITS HOUSING PROBLEM?

Just where and how big are the slums? How substandard are they, and in what ways?

Can part of the problem be solved by enforcement of reasonable housing codes?

What families need new housing, and how much can they pay for it?

These and other basic questions of housing policy can be answered with data from

AN APPRAISAL METHOD FOR MEASURING THE QUALITY OF HOUSING:

A Yardstick for Health Officers, Housing Officials and Planners

This is the survey technique, developed by the American Public Health Association's Committee on the Hygiene of Housing, of which Abel Wolman has said:*

> "It is one of the major contributions to translating opinion into objective measurement in one of the most difficult fields of appraisal."

Officially adopted by health departments in cities ranging from Battle Creek and Brookline to Milwaukee, St. Louis and Los Angeles, this method is now being promoted by the U. S. Public Health Service.

The Method is Completely Described in the Following Publications:

Part I. NATURE AND USES OF THE METHOD $1.00
This introductory volume is written for the policy-making official. In 53 readable pages, with many illustrations, it tells how practical housing programs can be shaped from an objective survey.

Part II. APPRAISAL OF DWELLING CONDITIONS $5.00
Three separate manuals give step-by-step instructions to the local survey director, the field crew and the office staff of a dwelling survey.

Part III. APPRAISAL OF NEIGHBORHOOD ENVIRONMENT In Press
Similar instructions are given for measuring the physical adequacy of neighborhoods.

Announcing the publication of

DIAGNOSTIC PROCEDURES IN VIRUS AND RICKETTSIAL DISEASES

This handbook, prepared by the Committee on Virus and Rickettsial Diseases of the Laboratory Section and edited by the Chairman of the Committee, Thomas F. Francis, Jr., M.D., details procedures which can be employed and interpreted by laboratory workers in the diagnosis of sixteen virus diseases. The diseases selected are essentially those of man for which procedures are available for use in a diagnostic laboratory.

Each of the sixteen sections has been written by an authority in the field. Much of the experience of each author has been contributed to his chapter and as a result the entire volume constitutes a compilation of methods proved by actual experience.

The volume has grown out of a recognized need for a publication of collected methods and has developed from a round table presentation at the Annual Meeting of the American Public Health Association in 1946. The methods are not presented as standards but are those most currently useful.

Members of the committee who have contributed and their subjects are as follows:

Psittacosis
K. F. Meyer, Ph.D., M.D. and B. Eddie, Dr.P.H.

Lymphogranuloma Venereum
Geoffrey Rake, M.B.

Trachoma and Inclusion Blennorrhea
Phillips Thygeson, M.D.

Variola and Vaccinia
Robert F. Parker, M.D.

Influenza
George K. Hirst, M.D.

Primary Atypical Pneumonia
A. E. Feller, M.D.

Mumps
John F. Enders, Ph.D., and Jeanette H. Levens, M.P.H.

Poliomyelitis
John R. Paul, M.D.

Encephalitis (Arthropod-borne Virus Encephalitides and Lymphocytic Choriomeningitis)
William McD. Hammon, M.D., Dr.P.H.

Rabies
H. N. Johnson, M.D., M.B., and Thomas F. Sellers, M.D., M.Sc.

Herpes Simplex
T. F. McNair Scott, M.D.

Yellow Fever
John C. Bugher

Dengue
Albert B. Sabin, M.D.

Phlebotomus (Pappataci or Sandfly) Fever
Albert B. Sabin, M.D.

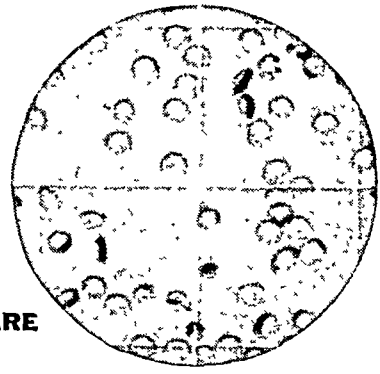
Only an ACCURATE Blood Count is Worth Taking

To aid in correct diagnosis and proper treatment of patients, a blood count *must* be accurate. That is why most technicians follow accepted techniques with utmost care . . . why they use only the finest equipment . . . why the majority choose the famous Spencer "Bright-Line" Haemacytometer.



Only BRIGHT-LINE Chambers offer these 6 Safeguards to Accuracy

GREATER CONTRAST BETWEEN CELLS AND BACKGROUND

Cells appear dark, lines bright, background gray. Each cell is easily counted—even those which overlap lines.

MORE EVEN DISTRIBUTION OF CELLS

Surface tension differences between metalized surface of chamber and glass surface of cover cause cells to distribute more evenly and chamber to fill more readily.

SIMULTANEOUS RESOLUTION OF BLOOD CELLS AND RULINGS

It is not necessary to stop down the condenser of your microscope since blood cells and rulings can be clearly resolved at full diaphragm opening.

METALIZED BACKGROUND ELIMINATES GLARE

Absence of glare provides clearer vision and reduces eyestrain.

INDENTATION OF UNDERSIDE PROLONGS USEFUL LIFE

Introduction of a slight concavity directly under rulings prevents scratches appearing on lower surface of chamber. Such scratches impair counting accuracy.

PRODUCTION TOLERANCES ARE HELD TO THOSE RECOMMENDED AND SET FORTH BY THE U. S. BUREAU OF STANDARDS

SPENCER

MEAT . . .

and Physical Rehabilitation

Any marked loss of weight in the nonobese patient deprives the organism of a considerable amount of protein, apt to lead to severe protein deficiency. A weight loss of 5 Kg. does not appear large as such. Yet it is estimated that it may well entail a simultaneous loss of as much as 900 Gm.—or two pounds—of tissue protein,* taken from the scant protein stores of the body, from the muscles, liver and other viscera. Prevention of such large protein losses or rapid replacement of depleted protein stores is imperative. Nitrogen balance must be re-established as quickly as possible to promote local healing and general recovery in many surgical conditions, in severe burns, in metabolic disturbances, and following overwhelming infections.

Meat as the primary source of protein affords a number of special advantages in the period of actual dietotherapy as well as during recovery and rehabilitation. It is of excellent digestibility so that it can be easily eaten two or three times a day to satisfy increased protein requirements.

The appetizing taste appeal encourages simultaneous intake of other valuable foods, especially desirable in the presence of anorexia.

All meat is notably rich in biologically complete protein, from 17 to 20 per cent of its uncooked and from 25 to 30 per cent of its cooked weight. Furthermore, meat ranks with the best sources of B-complex vitamins and iron, important nutrient factors in physical rehabilitation.

DIFCO

DETECTION OF THE
Typhoid-Dysentery
GROUP

° BACTO-S S AGAR

is a new selective medium especially designed for use in isolation of fastidious *Shigella* and *Salmonella* strains. The selective action of this medium restrains to a large extent the development of coliform bacteria with minimum restriction of fastidious strains of the typhoid-dysentery group. Because of the inhibitive action of the medium on coliform bacteria, it is possible to inoculate the medium heavily with feces thereby greatly increasing the chance of positive isolations from samples containing very few pathogens.

° BACTO-BISMUTH SULFITE AGAR

is a highly selective medium for isolation of *Salmonella typhosa*. The unusual selective properties of this medium permit the use of large inocula of feces and other suspected material without overgrowth of extraneous intestinal bacteria.

° BACTO-MACCONKEY AGAR

is an excellent differential medium for use in conjunction with Bacto-S S Agar and Bacto-Bismuth Sulfite Agar. This medium supports rapid and luxuriant growth of even the most fastidious strains of the typhoid-dysentery group. Although MacConkey Agar does not inhibit coliform bacteria it does afford excellent differentiation of colonies of pathogens from those of the lactose fermenting bacilli.

° BACTO-TETRATHIONATE BROTH BASE

is recommended for the preparation of Tetrathionate Broth to be used as an enrichment medium in the isolation of intestinal pathogens from stools and other suspected material. It is an excellent aid in detection of carriers and in determining the release of patients.

Alhydrox*

Builds solid immunity step by step

Like Mr. McGinty's brick wall which stands solidly against the ravages of time because he builds it carefully, solidly, brick upon brick, the immunity you build with CUTTER "ALHYDROX" vaccine is solid.

**Cutter trade name for aluminum hydroxide adsorbed products.*

"Alhydrox" *is a CUTTER exclusive*—developed and used exclusively by CUTTER for its vaccines and toxoids. It supplements the physician's skill by producing these immunizing advantages:

1. **"Alhydrox"** *adsorbed antigens are released slowly from tissue, giving the effect of small repeated doses.*

2. **"Alhydrox"**, *because of its more favorable pH, lessens pain on injection and reduces side reactions to a minimum.*

3. **"Alhydrox"** *selectivity controls the absorption of antigens, reducing dosage volume while building a high antibody concentration. Reduced volume means less tissue distention and less pain.*

penicillin in a flavored chicle chewing base

Penettes

a **new** and **different** dosage form for intraoral penicillin therapy

PLEASANT Here is Crystalline Penicillin G in a *pure chicle base*, as pleasant to use as the popular chewing gum confections. Peppermint flavored—entirely free from any penicillin taste or odor—this new dosage form will be welcomed by patients of all ages for whom intraoral penicillin therapy is indicated.

EFFECTIVE One PENETTE maintains a therapeutic concentration of penicillin in the saliva throughout the recommended half-hour chewing period, or up to as much as 2 hours if chewing is continued. Wide dispersion of penicillin throughout the entire oral cavity is assured by slow and regular chewing. A total of 4 to 6 PENETTES per day, combined with basic dental procedures as indicated, will normally arrest the majority of intraoral infections due to Vincent's or other penicillin-sensitive organisms within 24 to 48 hours.

Why not test PENETTES' *advantages yourself? A penny postcard will bring you a sample.*

Each Bristol PENETTE contains 10,000 units of Crystalline Potassium Penicillin G. They are available in convenient purse- or pocket-sized packages of 10.

PENETTES is Bristol Laboratories' trademark for Penicillin Chewing Troches in a flavored chicle base.

ELIMINATE THE HUMAN FACTOR
. . . in measuring hemoglobin
with the
FISHER ELECTRO-HEMOMETER

Rapid and accurate determination of hemoglobin in blood is possible with the Fisher Electro-Hemometer which operates on the acid-hematin principle. With this instrument, clinical examination becomes standardized because the human error of visual examination is eliminated. The direct reading scale shows the determination in both percentage of normal and grams per 100 ml. To the ease and accuracy of photometric measurement, the Electro-Hemometer adds speed and simplicity. No calculating is required and various operators achieve identical results. Supplied with this compact, portable unit are the photometric cell, standardizing cell, diluting pipette, the necessary batteries and printed instructions. Simplified operating directions are on the panel.

Electro-Hemometer, complete $90.00

Leather Carrying Case.....$9.00

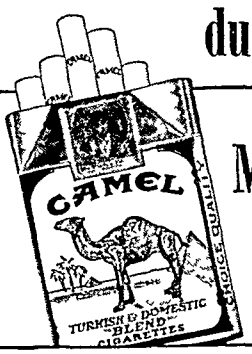
THROAT SPECIALISTS PROVE CAMEL MILDNESS IN 30-DAY SMOKING TEST

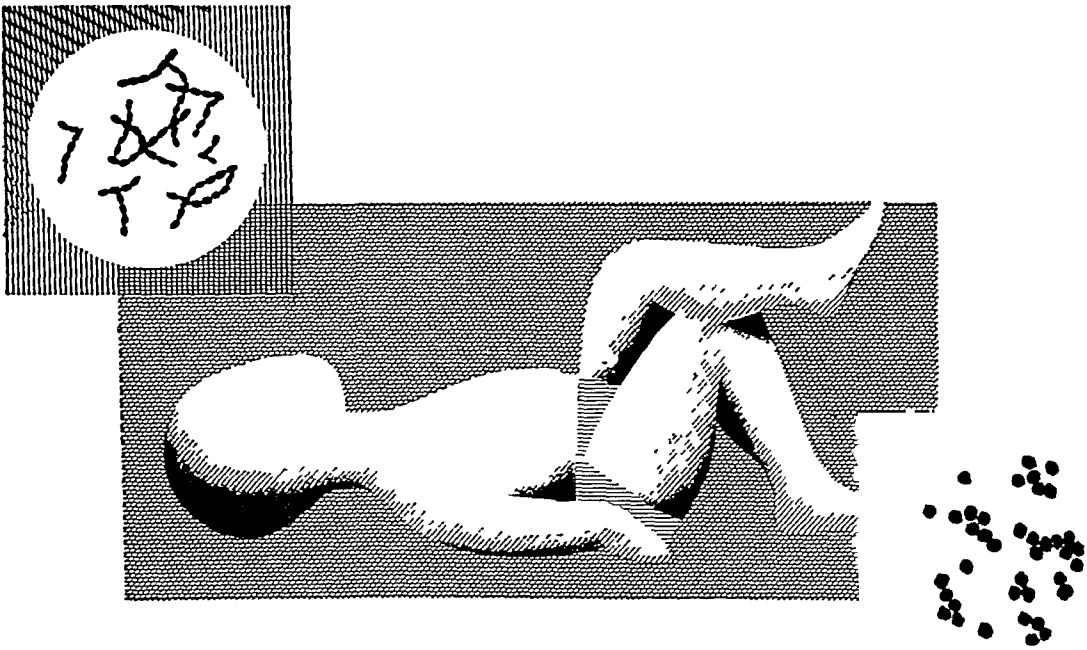


● In a recent coast-to-coast test, hundreds of men and women smoked Camels—and only Camels—for thirty consecutive days. They smoked on the average of one to two packages of Camels a day. Each week during the entire test period, the throats of these Camel smokers were examined by throat specialists. A total of 2,470 careful examinations were made. And after correlating these case histories, the throat specialists reported

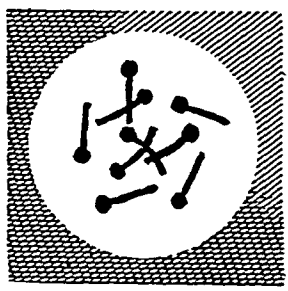
"NOT ONE SINGLE CASE OF THROAT IRRITATION due to smoking CAMELS."

MONEY-BACK GUARANTEE!

Try Camels and test them as you smoke them. If, at any time, you are not convinced that Camels are the best cigarette you've ever smoked, return the package with the unused Camels and you will receive its full purchase price, plus postage. (Signed) R. J. Reynolds Tobacco Co., Winston-Salem, North Carolina



According to a Nationwide survey:



MORE DOCTORS SMOKE CAMELS

than any other cigarette

When three leading independent research organizations asked 113,597 doctors what cigarette they smoked, the brand named most was Camel.

Three immunities with three 0.5 cc. injections

Protection against three organisms—C Diphtheriae, Cl. Tetani, and H. Pertussis—is conveniently provided by *Diphtheria and Tetanus Toxoids Alum Precipitated and Pertussis Vaccine Combined Squibb* given in three doses of 0 5 cc. each at monthly intervals.

Among its many advantages are:

Greater Convenience to patient and physician alike
Less Discomfort to the patient
Fewer Injections and hence lower expense to the patient
Lower Expense of administration for institutions and physicians
Pharmaceutical Elegance—milky suspension, exceptionally fluid.

DIPHTHERIA AND TETANUS TOXOIDS
ALUM PRECIPITATED
AND PERTUSSIS VACCINE COMBINED

In 1 5 cc vials, providing 1 complete immunization
In 7.5 cc vials, providing 5 complete immunizations

SQUIBB

Conservative Management WITH BACITRACIN

CSC

REDUCES THE NEED FOR INCISION

In the management of carbuncle and a host of other local cutaneous infections the early use of bacitracin greatly reduces the need for incision and drainage in a vast majority of patients. Injected directly into the lesion, bacitracin (500 U./cc. in sterile isotonic sodium chloride solution) exerts a profound antibiotic influence upon the invading pyogens. Bacitracin is particularly effective in the presence of penicillin-resistant staphylococci and streptococci, and in mixed infections. Topical administration of bacitracin solution hastens resolution, minimizes pain, and in most cases averts the need for local surgery.

Bacitracin, topically administered, is a valuable means of treating a wide variety of local infectious processes. Physicians are invited to send for descriptive literature.

SUPPLY

Bacitracin-C.S.C. is supplied in 20 cc. size rubber-stoppered vials containing 2,000 and 10,000 units, and in 50 cc. rubber-stoppered vials containing 50,000 units.

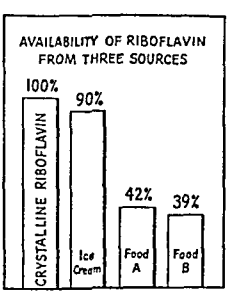
Spotlight on the Riboflavin in Ice Cream



Here is evidence that the riboflavin in ice cream is almost completely available for use by the body.

It was discovered recently that by actual analysis the riboflavin content of ice cream is much higher than previously believed. This is important news but it is only the first chapter of the story.

Other recent research proves that riboflavin occurs in ice cream in a form that the body can use efficiently. A study conducted by Everson and co-workers* in which college women served as experimental subjects, shows that the riboflavin of ice cream is almost 100% available to the human body.

> When a supplement of riboflavin was furnished by ice cream, it was nearly as well absorbed as the vitamin in its pure crystalline form and better than that in two other test foods studied. These facts are illustrated in the chart below.

The presence of nutritive constituents in foods is not alone sufficient to insure proper nourishment. Nutrients also must be in a form which can be assimilated readily and put to use by the body. It is increasingly apparent that *availability* of nutrients is just as important as is actual nutrient *content* in selecting foods for specific dietary recommendations. It is reassuring to know that, as to riboflavin, ice cream ranks high on both counts. This is important for everyone concerned with planning nutritious diets, whether to please normal appetites, or the often difficult appetites of the ill and the aged.

*Everson, G., Wheeler, E., Walker, H., and Caulfield, W. J. *Availability of riboflavin of ice cream, peas and almonds judged by urinary excretion of the vitamin by women subjects.* J. Nutr. *35*:209 (Feb) 1948.

Don't be your age

To all who want to look and feel younger than they are, nutrition research offers sound advice

EVERYONE knows that science has increased the number of years we can expect to live. We are learning, also, to make the extra years count. Good nutrition is one important factor in extending the period of adult vitality.

Recent research makes it apparent that, while aging persons may need less calories because of decreasing energy requirements, it is highly desirable for their health and happiness to keep the nutrients in their diets at a high level.

Learn from nutrition research—Ohlson and associates* have studied groups of older women. Important observations were made as to their dietary habits, their physical status, and their need for protein, calcium, and phosphorus. These older women were found to need protein for maintenance of body tissues just as much as younger women. If they omitted milk from their diets, their intakes of protein and of other nutrients suffered.

Approximately one gram of calcium daily was found to be necessary, on the average, to keep these older women in calcium equilibrium. However, since calcium is not abundantly distributed among foods, the women received this amount of calcium only if their diets contained liberal amounts of milk and milk products. The calcium content of the women's diets was directly related to the amount of milk they consumed.

Many adults, especially women, show a considerable degree of demineralization of the skeletal structure by the age of fifty. This condition may lead to broken bones and the familiar stoop shoulders of old age. The precise mechanism requires further study.

Make your extra years count—In the study, the groups of women considered to have good health tended to drink more milk, eat more vegetables, whole-grain cereals, and eggs than women in corresponding poor health groups. The study suggests that ill health may be associated with food intakes that are unsatisfactory in quality and quantity. But the authors point out that while ill health itself may result in reduction of food intake, the symptoms of ill health also may be exaggerated by inadequate food.

As the American life span increases, the need to guard the health of older citizens grows more and more vital. Good nutrition constitutes one important factor of protection. Liberal consumption of milk and its products is one basic step toward good nutrition.

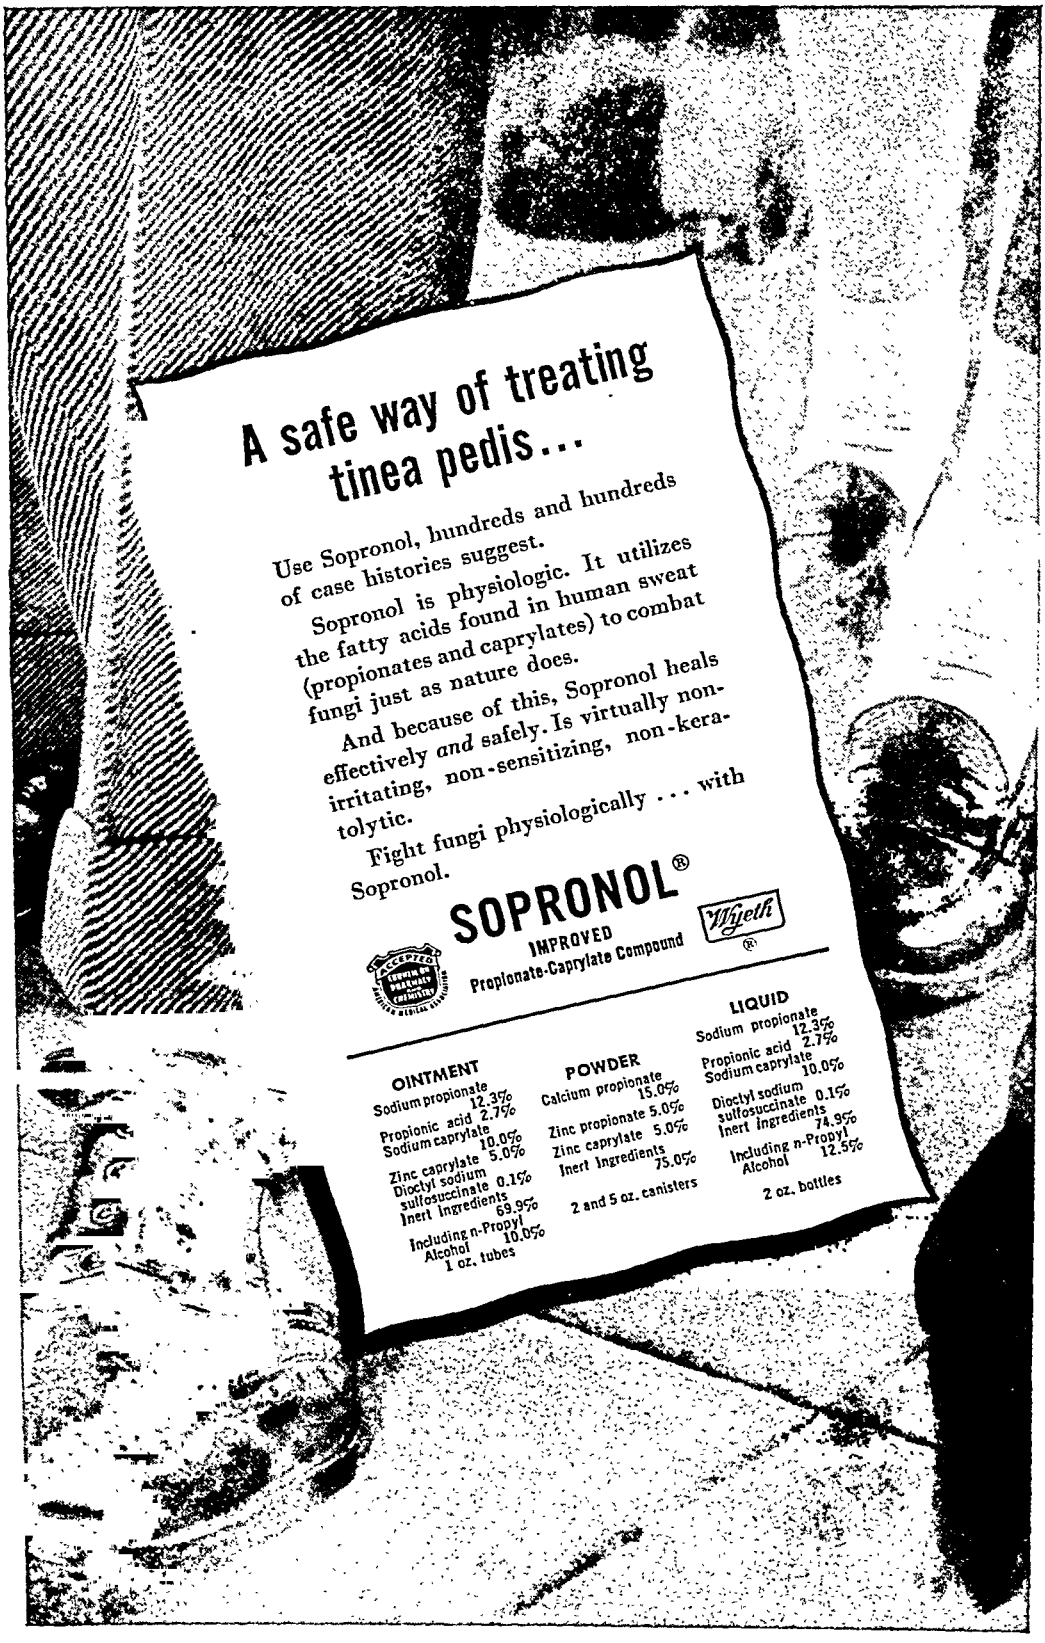
Prevent dangerous errors in blood typing

BROWN BLOOD BOARD

Cuts down errors in blood grouping, Rh typing, Rh sensitivity testing and cross matching for transfusion by combining the latest approved technics into a simplified, organized procedure. . . . In emergency, permits accurate determinations by doctors or technicians not normally responsible for such testing.

The Brown Board outfit [1] consists of an etched and stamped metal plate on a hardwood base, with an Rh typing box,[2] adapters designed to hold any commercial anti-serum bottle, reagent bottles, test tubes, dropping pipettes and concavity slides for Rh typing. Adapters and reagent bottles are designed to permit one-hand removal and replacement of the dropping pipettes.

To cut down errors, the reagent bottles, adapters and tubes are permanently marked in different colors which match the labelling and coloring of their respective positions in the Board; their sizes or shapes also differ, so that they can fit only in their own positions. A slot in the Board holds the Donor Card and Transfusion Request Form in front of the technician while tests are being made.



Brown Blood Board, complete with Rh typing box, anti-serum bottle adapters, reagent bottles, test tubes, dropping pipettes and four-concavity slides for Rh typing.....**A-2800** each **$90.00**

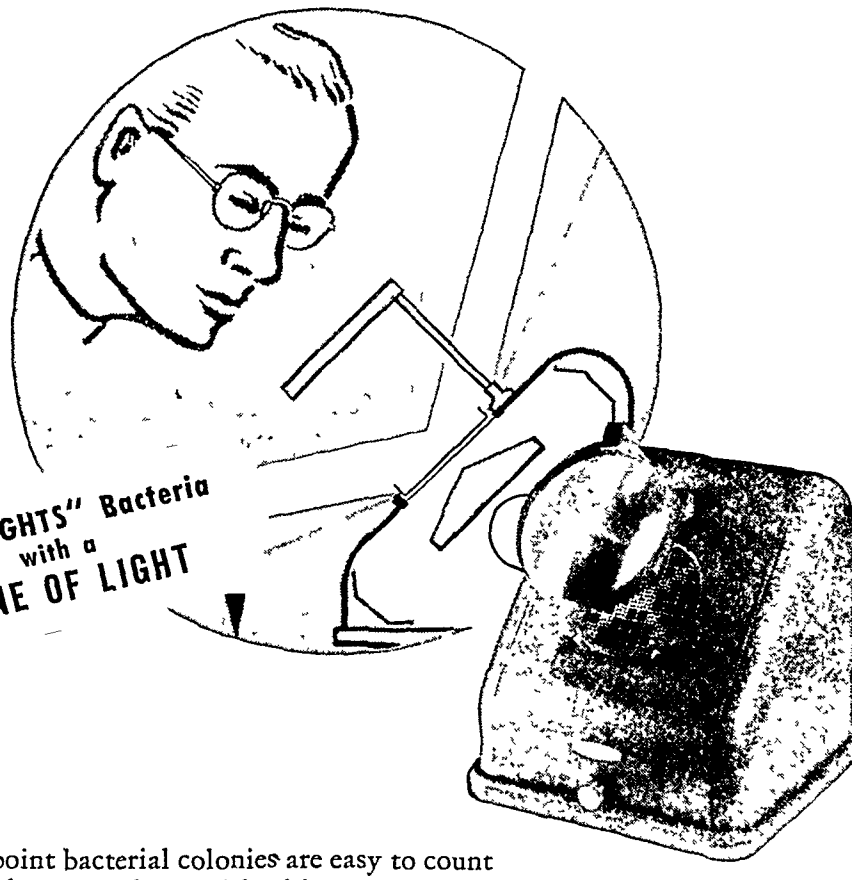
Warmth Without Weight

Scientific progress has reached out to so many fields in the past few years. that people in all walks of life have benefited. The Uniform Clothing field has been prominently affected by scientific advancement.

SMITH-GRAY has kept abreast of every development, and is now proud to introduce to the field of Public Health Nurses uniform clothing, a coat which will provide WARMTH WITHOUT WEIGHT.



This is accomplished by a lining which was developed during the last war by the United States Army Arctic Clothing Program. This remarkable lining, although light as a feather, insulates the coat so completely that a lighter weight material may be used for the coat and still provide perfect WARMTH WITHOUT WEIGHT.

SMITH-GRAY has made exhaustive experiments during the past winter, and has put this remarkable lining to severe test. We have used it extensively in coats made of lighter than usual material, subject to hard usage, and worn by individuals whose occupations expose them continually to severe climatic conditions.

With pride, we now offer this scientific achievement to Public Health Nurses everywhere. To each we say: —The incorporation of this lining in your next winter's SMITH-GRAY coat will bring you WARMTH WITHOUT WEIGHT!

NEW SPENCER COLONY COUNTER

Even the pinpoint bacterial colonies are easy to count —quickly and accurately — with this new Spencer Dark Field Quebec Colony Counter. Employing the principle of the dark field microscope, it has a unique annular reflector which illuminates the specimen symmetrically with oblique rays of light and leaves the background subdued. As a result it provides:

1. **Remarkably uniform illumination**— the colonies are lighted from all sides.

2. **Greater brilliance**— reflector collects and concentrates the light rays.

3. **Freedom from glare**— only light reflected from the specimen reaches the eyes of the observer.

4. **Enclosed illuminating system** — protected from dust, yet permitting easy replacement of the household 40 watt lamp.

Equipped with a standard 1.5x lens, this compact, efficient instrument will be welcomed by health departments, hospitals, dairies, breweries, canneries— wherever colony counts are made. Write dept.T-19 for details.

Neglect of Breakfast

MAY MEAN

Neglect of Health

AN ADEQUATE breakfast is the first step of the day towards adequate nutrition; good nutrition in turn is excellent assurance for maintenance of health. The skipped or skimpy breakfast not only deprives the body of needed morning nourishment, but threatens both the adequacy of the day's diet and the general well-being.

The foods customarily eaten at breakfast—fruit or fruit juice, cereal, milk, bread and butter—are also the foods comprising a basic breakfast pattern which has found wide endorsement by nutrition authorities. This breakfast pattern provides well-balanced nourishment: proteins of high biologic value, carbohydrate energy, vitamins, and minerals. The easy digestibility, excellent nourishment, and tastiness of the cereal serving—breakfast cereal,* milk, and sugar—make it a favored food in the morning meal in convalescence and in health.

The many kinds of breakfast cereals add welcome variety of form, texture, and appetite appeal to the cereal dish.

BASIC BREAKFAST	TOTALS supplied by Basic Breakfast		AMOUNTS supplied by cereal serving
Orange juice, 4 fl. oz.;	CALORIES	611	202
Ready-to-eat or Hot Cereal, 1 oz.;	PROTEIN	20.7 Gm.	7.1 Gm.

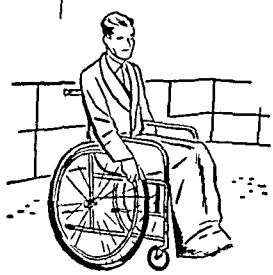
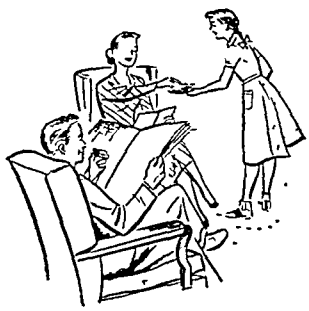
Eskimos have a novel system of milk storage. They freeze their reindeer milk, hack off a hunk and melt it as needed. The system is neat . . . but hardly clean . . . and wide open to germs causing milk-borne diseases.

Americans prefer the single-trip system of Canco flat-top Paper Milk Containers . . . the safe, sanitary system Public Health officials have sanctioned so widely.

1. **Single-trip** feature breaks chain of possible milk-borne infections!
2. **Rinse tests** reveal no Escherichia coli, and a high percentage of complete sterility in containers delivered to the dairy.
3. **Opened, filled,** and closed in minimum time by machines!



CANCO



American Can Company New York, Chicago, San Francisco

DELICIOUS *Candy*

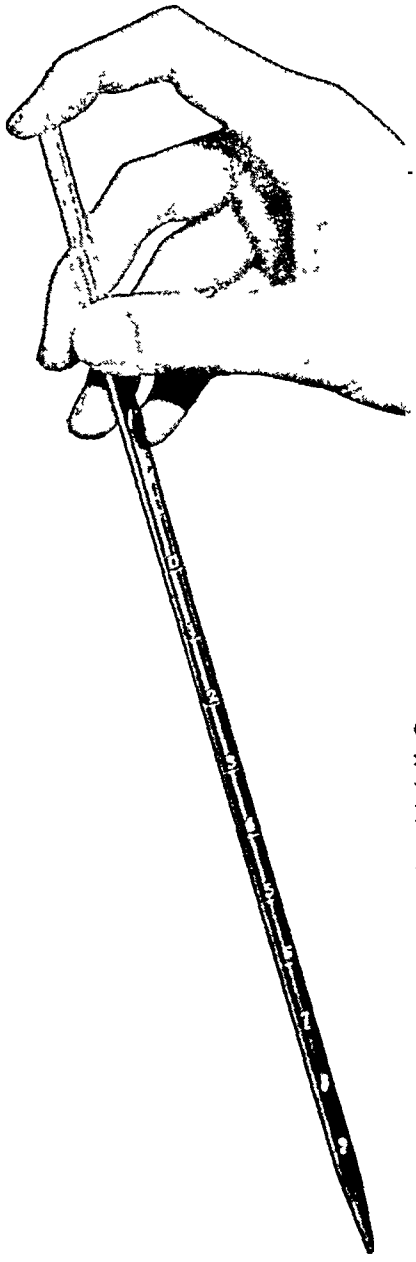
FOR MANY USES IN THERAPEUTICS

Candy, widely used empirically in medical practice by the ancient physicians, is employed therapeutically today in its many forms on a sound rational basis.

Hard dextrose candies, providing concentrated carbohydrate food energy, are particularly useful as a source of carbohydrate in the treatment of liver and other diseases. Medicated candy is widely employed in oral and respiratory infections, and is especially applicable for administering distasteful drugs to both children and adults. Candies, appealing in taste, cheer the convalescent patient, thus encourage a more favorable outlook by a direct psychosomatic approach.

Many candies also contain milk, cream, butter, eggs, nuts and peanuts—all valuable food ingredients. Such candies, to the extent they provide these component foods, supply biologically desirable protein, vitamins and minerals.

Candy in moderation is wholesome food in the adequate diet of both children and adults.



THE NUTRITIONAL PLATFORM OF CANDY

1. Candies in general supply high caloric value in small bulk.
2. Sugar supplied by candy requires little digestive effort to yield available energy.
3. Those candies, in the manufacture of which milk, butter, eggs, fruits, nuts, or peanuts are used, to this extent also—
   (a) provide biologically adequate proteins and fats rich in the unsaturated fatty acids;
   (b) present appreciable amounts of the important minerals calcium, phosphorus, and iron;
   (c) contribute the niacin, and the small amounts of thiamine and riboflavin, contained in these ingredients
4. Candies are of high satiety value; eaten after meals, they contribute to the sense of satisfaction and well-being a meal should bring; eaten in moderation between meals, they stave off hunger.
5. Candy is more than a mere source of nutriment—it is a morale builder, a contribution to the joy of living.
6. Candy is unique among all foods in that it shows relatively less tendency to undergo spoilage, chemical or bacterial.

PIPETTES...

Quickly readable, unaffected by repeated sterilization

Clinical research makes many demands on the technicians in charge. Speed is one of them. But speed without accuracy avails nothing. That's why PYREX brand Pipettes are designed for easy readability. The "Lifetime Red" graduations are permanent, part of the pipette body itself. "Lifetime Red" will not wear or chip off in long service. Tips are fabricated to give maximum protection from chipping.

Made from PYREX brand glass No. 7740, they withstand repeated sterilization (wet or dry). They are unaffected thermally or chemically by any of the methods normally employed in laboratories where sterilization is a major factor in routine or in specialized work.

The measuring and serological types more than meet the tolerances of Federal Specification D.D. V-581 in regard to accuracy limits. When you call your laboratory supply dealer, ask for PYREX brand Pipettes!

BREAK-POINT HELPS THIS WEST COAST WATER WORKS

Typical of what Break-Point Chlorination can accomplish is this case history.

A 1½ mgd. west coast water works using an impounded supply was troubled by summertime odors so acute that settling basins had to be washed almost continuously, while in the winter, color ran as high as 600 ppm. To overcome these troubles, several treatment methods were tried—unsuccessfully. Then W&T Engineers, in cooperation with the plant staff, carefully analyzed the situation. At their suggestion, the Break-Point Process was employed, using W&T Chlorinators for pre-chlorination. With this treatment, according to a report by staff members, color troubles, together with complaints concerning iron and manganese stains, were eliminated; filter runs increased; and summertime odors cut almost to the vanishing point.

In addition to such direct chlorination benefits, when you call on W&T you have the added assurance of W&T's 35 years of chlorination experience—a full line of chlorinators from which to choose—the backing of extensive research and development facilities—and finally, a top-notch, alert field organization at your call for prompt service and technical assistance.

For more details, ask your nearest W&T Representative —he'll be glad to help you.

The W&T Residual Chlorine Recorder is especially valuable in securing the best possible results with the Break-Point Process

Diagnostic Problems in Medical Mycology*

C. W. EMMONS, PH.D.

Laboratory of Infectious Diseases, Microbiological Institute, National Institutes of Health, Bethesda, Md.

THE laboratory diagnosis of mycoses is a problem of interest to clinicians as well as to laboratory workers. There are certain inadequacies and pitfalls inherent in current laboratory methods of detecting fungus infections which sometimes delay a differential diagnosis and which seriously limit our knowledge of the epidemiology of the mycoses.

The diagnosis of systemic fungus infections has aroused increasing interest during recent years, yet, although some improvements have been made, I know of no radically new dependable diagnostic methods in medical mycology. The diagnosis of a mycosis still rests upon one or, preferably, both of two procedures, the actual demonstration of the fungus in tissue or exudate and its isolation in pure culture with a specific identification of the fungus. The clinical variability of mycoses is notorious, so that even in superficial skin lesions of the hands and feet a laboratory diagnosis is desirable in the differentiation of dermatophytosis and dermatitis. In the case of pulmonary mycoses the roentgenologist finds it difficult to make more than a provisional diagnosis, for, although some fungi seem to show a predilection for certain lung areas, the diversity of lesions produced by even a single fungus makes the x-ray diagnosis at best probable rather than definitive. Serologic methods of diagnosis, in spite of improvements in techniques, remain only adjuncts to the direct demonstration of pathogenic fungi. The laboratory diagnostician, therefore, still needs to recognize and know individual fungi.

Methods of searching for, isolating, and recognizing fungi are described in so many texts that it would be repetitious to discuss here, one by one, the various mycoses and the laboratory procedures involved in the diagnosis of each. It may be worth while, however, to discuss some particular problems commonly met.

It would appear from an appraisal of the fungi which reach my laboratory for identification that lack of familiarity with the common saprophytic fungi is a frequent source of confusion. A bacteriologist who would discard at once a single colony of *Staphylococcus* ap-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

pearing in a culture from a skin ulcer or from sputum may send for identification a *Penicillium* or an *Alternaria* which has appeared under such circumstances. The spores of fungi are freely air-borne, and viable spores of harmless fungi may fall into the culture or may be found in considerable numbers on skin surfaces or even within body cavities. The protective mechanisms of the body are not able to destroy promptly spores of some of these harmless saprophytic fungi. This can be demonstrated readily by injecting spores into a laboratory animal and recovering them in culture, sometimes weeks later, even though there has been no growth or multiplication in the experimental animal. Therefore, growth of saprophytic fungi in cultures made from exposed lesions is to be expected.

Viable spores of fungi are also inhaled in great numbers and may grow in cultures made from subsequently cultured sputum. The isolation of saprophytic fungi from sputum is therefore a common experience and these fungi may be of no more significance than the multitude of saprophytic bacteria also present. If one is searching for a fungus in pulmonary disease it is as important to differentiate probable pathogens and probable saprophytic contaminants among the fungi as among the bacteria. However, there are some saprophytic fungi which are occasionally pathogenic.

The importance of an accurate specific identification of fungi can be illustrated by a discussion of a fungus which is a member of a large genus most species of which are of no medical importance. This fungus, *Aspergillus fumigatus,* is a common saprophyte, yet it can, on occasion, cause pulmonary disease. Most of the green and gray-green fungi isolated from sputum will be other species of *Aspergillus* or *Penicillium* and only a careful examination of the fungus will enable one to recognize this particular species. This fungus is commonly present in superficial soil layers and in decaying vegetation. In a search for mycoses in rodents I have very often isolated it from the lungs of these animals although no gross or microscopic lesions could be found. Presumably the colonies appearing in these cultures come from recently inhaled spores. In cultures of human sputum the fungus sometimes appears, but I should attach no importance to a single or to occasional colonies appearing in a series of cultures unless there is supporting evidence of an etiologic relationship. Such evidence might consist of its appearance in large numbers in cultures made from several sputa collected with due precautions against contamination. If the patient has been working or living in a dusty environment, this may explain the appearance in culture of an occasional colony of this fungus. More convincing evidence of an etiologic relationship is furnished by the direct microscopic demonstration of typical hyphal fragments in the patient's sputum. The contorted, frequently septate, and often somewhat encrusted structure of these fragments, indicates that they actually grew in the lung and were not merely air-borne fragments recently inhaled.

The yeast-like fungus, *Candida albicans,* poses a different problem. It is not commonly air-borne but, on the contrary, may be considered as almost a normal inhabitant of the body cavities. *C. albicans* is commonly present as a secondary invader in sputum in almost every type of pulmonary disease, and it can be temporarily eliminated by iodides or gentian violet without affecting the course of the disease. It is capable of causing thrush and may modify pulmonary disease of other etiology, or in rare cases, be of primary importance. Usually, however, its isolation in sputum cultures is of no significance. Its abundance in a sputum specimen is significant, only if precautions are taken to avoid contamination

from the mouth and if the specimen is examined at once. *C. albicans, Fusarium, Cephalosporium,* and some other fungi multiply rapidly in sputum held at room temperature after collection. A 24 hour specimen or a specimen mailed to a laboratory is unsatisfactory, if not worthless, for mycological study. Even after isolation of *C. albicans* from a fresh sputum specimen and its specific determination by appropriate methods the question of its etiologic importance remains. Certainly, in most cases, another primary etiology can eventually be found.

I have mentioned two saprophytic fungi which under certain circumstances can become pathogenic, and some criteria more or less useful in judging their importance. There are other fungi which are without pathogenic properties but which present important diagnostic problems because of their resemblance to pathogens. Some of the Basidiomycetes or mushroom fungi which frequently appear as contaminants in sputum cultures are confusing because in colony appearance and in microscopic morphology they resemble the important pathogen, *Coccidioides immitis*. An examination of these fungi serves to illustrate the dependence mycologists place upon morphology in the identification of fungi. Many Basidiomycetes produce spores which are called oidia and are formed by the fragmentation of hyphae of haploid mycelia. There is nothing distinctive about them except that in some species they are borne on somewhat specialized terminally branching hyphae. They bear a superficial resemblance to the chlamydospores of *Coccidioides immitis* which, however, differ from them in certain important respects. The spores of *Coccidioides* are borne on special hyphae or conidiophores in which the fertile portion is nearly twice the diameter of the vegetative hypha from which it originates, the spore chains are constricted at the septa which separate spores, and there is a condensation of protoplasm within the hyphal segment which results in a chain of spores separated by empty spaces. This morphological differentiation is especially important because of the resemblance between the two fungi in culture.

One further problem associated with the recognition of pathogens involves poorly known fungi which cause the rare mycoses. A good example would be one of the rare types of mycetoma, in some of which the isolation of the fungus in culture is difficult or has been accomplished only a few times. In such cases there may be doubt about the identity of the fungus involved as well as about its etiological relationship. Here, one needs adequate amounts of material, from pus or biopsies, in order to determine as a preliminary step whether the fungus is actually growing in the lesions. Some ten years ago I received for identification an unfamiliar fungus which I identified as a *Fusidium*. It had been isolated from a lesion clinically typical of actinomycosis, but it was isolated only once and was not demonstrated in the tissues. I did not see another strain of this fungus until recently, when the same species was isolated from enlarged axillary nodes and submitted for identification. In the second case careful examination of stained sections failed to demonstrate the fungus but an acid-fast bacillus was isolated in culture and demonstrated in sections of nodes. It was concluded that the fungus was a culture contaminant in both these cases, but it is not a familiar contaminant and if it had been isolated repeatedly and found upon direct examination in pus or tissues further study might have justified another conclusion.

One of the practical problems confronting the laboratory diagnostician in the examination of pathologic material is the recognition of artefacts resembling fungus structures. In the case of dermatophytosis one of the most troublesome

is the so-called "mosaic fungus" which is actually an accumulation of cholesterol in the interstices of epidermal cells. There may be a superficial resemblance to fungus hyphae and, in fact fungi may be found associated with the mosaic. However the mosaic, as the name indicates, forms a network pattern extending around epidermal cells, the individual parts vary abruptly in diameter, and flat crystals with reëntrant angles can frequently be observed.

The so-called "myelin globules" present in large amounts in certain types of pus and sputum often assume forms suggesting budding fungi and hyphal fragments. It is usually possible to recognize these readily by observing the bizarre forms present, the laminated structure, and the increase in size or numbers of these bodies after the material is mixed with a sodium hydroxide solution. Other structures appearing in sodium hydroxide preparations of pus or sputum are clusters of fatty acid crystals and bacterial colonies which may be mistaken for the granules characteristic of actinomycosis.

There have been hopeful attempts to achieve shortcuts such as the use of culture media which will support growth of pathogens and inhibit saprophytes, but there is no satisfactory substitute for an acquaintance with the fungi and the circumstances under which they appear in cultures made from pathologic tissues or exudates. It is useful to know and recognize the characteristics of saprophytic fungi. It is essential to know and recognize the characteristics of the pathogens.

In the preparation of differential culture media for the isolation of pathogenic fungi there have been some useful advances. The first practical use of an antibiotic was in the preparation of selective culture media. Since pathogenic fungi, with the exception of *Actinomyces bovis*, are resistant to penicillin and streptomycin, the addition of 20 units per milliliter of each of these to a culture medium inhibits the bacteria which may be present in pus or sputum but permits the growth of fungi. The use of this medium, and of media containing other bactericidal ingredients, permits the ready isolation of fungi from ulcers and sputum in cases where more rapidly growing saprophytic bacteria would otherwise inhibit growth of pathogenic fungi. Robbins,[9] Georg,[4] Mackinnon,[6] Benham,[1] and others have obtained information about vitamin and growth factor requirements of some of the dermatophytes which have led to the improvement of culture media and new criteria for the limitation of species. Salvin[10] has determined the amino acid and vitamin requirements of *Histoplasma* and other pathogens and the influence of these nutritional factors upon the growth types of diphasic fungi.

The need for specialized knowledge and experience in the laboratory diagnosis of mycoses by recognition of the fungi has led to continued attempts to substitute for the actual demonstration and identification of fungi less direct diagnostic procedures. One of the most convenient of such procedures is the intradermal test which is based upon the well known principal that, as in many bacterial diseases, a cutaneous sensitization follows many fungus infections. If this sensitization were specific and if a specific antigen could be prepared from the fungus causing it, a cutaneous reaction to the intradermal injection of the antigen would have considerable diagnostic significance. The usefulness of such a specific test would be limited only by the fact that acquired cutaneous sensitization may persist for many years; consequently, a reaction may refer to an earlier infection rather than to the present condition which is under consideration.

The pioneer studies of cutaneous sensitization induced by the dermatophytes made by Bloch, Jadasshon, and their

students date from 1925 and many investigators have produced an enormous literature on the subject which I shall not attempt to review. Trichophytin, so far as I am aware, has little use as a diagnostic agent at the present time although there is still interest in it from the experimental viewpoint in some laboratories. Coccidioidin has had a very useful application to epidemiologic studies of coccidioidomycosis. Most of the coccidioidin used has been prepared by Dr. C. E. Smith[12] who has carefully tested the material, utilizing only those lots which give a minimum of nonspecific reactions. Recently acquired coccidioidin sensitivity is generally accepted as diagnostic of coccidioidomycosis even though the patient may have remained asymptomatic and the fungus cannot be demonstrated in exudates. Antigens for use in skin testing have been prepared from many other pathogenic fungi. Most of these have had a very limited use and adequate studies of specificity have not been carried out. One fungus antigen, histoplasmin, first prepared by Van Pernis, Benson, and Holinger in 1941,[13] has been widely used in epidemiologic studies. Histoplasmin is not specific, since laboratory animals can be sensitized to it by experimental infection with other fungi.[3] Howell[5] believes that by use of a critical dilution of histoplasmin a diagnostic interpretation can be made. The subject is of considerable medical interest because of Christie and Peterson's[2] and of Palmer's[8] demonstration of a correlation between histoplasmin sensitivity and the occurrence of non-tuberculosis pulmonary calcification and because of the high incidence (80–90 per cent) of histoplasmin sensitivity in some geographic areas. The interpretation of the histoplasmin skin reaction is equivocal, and in my opinion the diagnosis of histoplasmosis based on a cutaneous reaction to histoplasmin is not justified at the present time

Agglutinins, precipitins, and complement-fixing antibodies have been sought in human mycoses and in experimentally infected animals by many investigators during the past 40 years. The accumulated evidence seems to indicate that these serologic methods have a very limited usefulness in the practical diagnosis of mycoses. Martin[7] and his associates failed to find complement-fixing antibodies in a considerable number of patients with proved blastomycosis and particularly in those with localized cutaneous lesions. They did not attempt to increase the sensitivity of the antigen because of the inherent uncertainties of the method and the relative ease of making a definite diagnosis by mycologic examinations. They considered that the test had some prognostic value since they observed, as has Smith in coccidioidomycosis, that a rise in titer indicates generalization of the infection. In the case of the most pressing diagnostic problem in mycology, that of the possible occurrence of a prevalent mild form of histoplasmosis, serologic methods have not as yet been helpful. Salvin and Hottle's[11] report of the rise and subsequent fall of titer and eventual disappearance of complement-fixing antibodies in experimentally infected rabbits and our failure in field studies to find them in sera from individuals with strong skin reactions indicate that in histoplasmosis, as in other mycoses these methods may not be of value in the diagnosis of mild or healed cases.

WHO on Maternal and Child Health

The report of the first session of WHO's expert Committee on Maternal and Child Health held in Geneva, January 24–29, is now available. Martha M. Eliot, M.D., its United States member, was unanimously elected Chairman and Dr. Marion Yang, the Chinese member, Vice-chairman. Other members represent Belgium, Czechoslovakia, India, Mexico, Turkey, and the United Kingdom.

Among the actions taken was the increase in the committee's membership to 12. Recommendations called for the establishment of an information bureau in the Maternal and Child Health Section to meet the widespread demand from many countries on various aspects of maternal and child health; that a health education service be developed in WHO; that coöperation between the Section and FAO and UNICF continue to provide supplies for child health programs, particularly clean and safe milk supply everywhere, and for nutrition work, particularly in rural areas; that mental health be included in the maternal and child health program; that the staff of the Section be increased to give countries assistance with demonstration teams, visiting consultants, research development of rural programs and those for handicapped children; that governments be urged to introduce compulsory immunization for children against such diseases as smallpox and diphtheria; that all possible action be taken to relieve the world-wide shortage of nurses; and that maternal and child health services be organized in underdeveloped areas.

The meeting discussed means by which pediatricians who would not otherwise be able to do so might be supplied with funds to attend the International Congress of Pediatrics, to be held in Zurich, July 24–29, 1950. In connection with the Congress a child health exhibition will be held from July 20 to August 5. The expert Committee recommended that WHO participate in planning an exhibition to demonstrate a maternal and child health program with particular reference to the function of the public health nurse and the midwife.

Histoplasmin Sensitivity Among Cattle*

MICHAEL L. FURCOLOW, M.D., AND JOSEPH S. RUHE, D.V.M.

Surgeon, and Public Health Veterinarian, U. S. Public Health Service,† Kansas City, Kan.

SINCE Ruhe and Cazier [1] have recently reviewed the occurrence of histoplasmosis in animals, no attempt will be made to review the literature. The disease has been reported in rats, mice, dogs, ferrets, and possibly a horse. The importance of these casual observations of infected animals in the epidemiological picture is difficult to evaluate because of the lack of a sufficient size sample of animals or of adequate diagnostic technic.

There have been, however, several serious attempts to find an animal reservoir of this disease. Emmons and his group [2, 3] have concentrated on attempts to isolate the organism from the tissues of wild or domestic animals. They reported the isolation of the organism from one house mouse (out of almost 1,000 studied), from 16 rats (*Rattus norvegicus*) (an average of 2.8 per cent), but negative results from numerous other animals such as woodchucks, rabbits, various species of mice, etc.

Our studies have been concentrated in the main on another approach to the problem, namely, the distribution of skin sensitivity to histoplasmin, an extract of the fungus *Histoplasma capsulatum*. The present paper reports studies in histoplasmin sensitivity among cattle and a comparison of this sensitivity among cattle and children in the same county in Kansas. We were first led to study cattle by the chance finding that of 13 head living on the farm of one of our suspected human histoplasmosis cases, two reacted to histoplasmin. Large scale studies were then done, at first with the active coöperation of Dr. Philip Cazier of the Bureau of Animal Industry, Department of Agriculture, whose assistance is gratefully acknowledged.

The tests were performed in most cases at the same time as tuberculin tests. No cross-reactions with tuberculin were found. One-tenth ml. of histoplasmin was injected intracutaneously in the caudal fold. Tests were read at 72 hours. A positive reaction was evidenced by an edematous swelling at the site of inoculation which was easily palpated and usually clearly visible.

The histoplasmin (Lots H-15 and H-40) was furnished by Dr. Arden Howell, Public Health Service. For the early tests, the same lot of histoplasmin (H-15), which had been extensively employed in tests on human beings, was used. The dilution of antigen to be used in cattle was arrived at empirically on the first farm tested. A dilution of 1 to 100 was first used and no reactions were noted in the 13 cows tested. When the herd was retested with a dilution of 1 to 10, 2 cows showed strong reactions, while none of the others showed any reaction. Lot H-15 was accordingly employed in a

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

† From the Office of Field Studies, Division of Tuberculosis and Veterinary Public Health Division of Communicable Disease Center.

dilution of 1 to 10 in tests on 589 head of cattle in eastern Kansas. Because of a shortage of Lot H-15, it was necessary to employ Lot H-40 for the remainder of the study. Since H-40 was known to be slightly weaker than H-15, it was employed in a dilution of 1 to 5. Twelve hundred and eighty-five cattle throughout the state, including all those tested in Shawnee County, received this test dose.

A total of 1,874 cattle were tested in Kansas. Approximately 22 per cent of these were beef cattle and 78 per cent were dairy cattle. In the eastern third of the state 1,319 head were tested with 4.2 per cent showing positive reactions, in the central third, 136 were tested with 1.5 per cent positive, and in the western third, 419 were tested without finding a single positive. Study of these results indicates that histoplasmin sensitivity in cattle falls off as one moves westward in Kansas. A similar falling off in histoplasmin sensitivity in human beings in Kansas was shown earlier by Bunnell and Furcolow.[4]

A more detailed analysis of the comparison of histoplasmin sensitivity among human beings and cattle was attempted in Shawnee County, Kansas, a county in the eastern third of the state in which the state capital, Topeka, is located. Over 1,100 children had been tested in Topeka and their rate of reaction to histoplasmin was known.[4] For comparison with the cattle, only records of those children less than 13 years of age were used.

In Shawnee County 432 cattle were

tested. These cattle were distributed among 23 farms as illustrated in Figure 1. They ranged in age from less than 1 year to 16 years. Relatively few cattle over 9 years of age were tested. Table 1 shows the comparison of the histoplasmin skin test results on these 432 cattle compared to 423 children who were 12 years of age or less. In Figure 2 the comparison is shown graphically. From this figure it is evident that there are marked similarities in reaction rates between cattle and children of similar age.

A peculiarity was noted in the cattle testing, the significance of which is not clear. In the original studies, approximately 282 cattle on 21 farms scattered throughout the county were tested. Because of the interesting results obtained, an additional 150 head of cattle were tested from two institutional herds located on the outskirts of Topeka. The results of tests on these two institutional herds are tabulated separately in Table 2 as they are quite different from those obtained with the scattered farm testing, since only 2 of these 150 cattle, or 1.3 per cent, were positive to histoplasmin. Of the scattered 282 cattle tested on 21 premises, 7.1 per cent were positive to histoplasmin. The peculiar epidemiological characteristics of the two institutional farms compared with the remainder of the county are under investigation at present. So far no lead has been uncovered to explain the differences in histoplasmin reactors.

In summary, it is evident that histoplasmin reactors occur in cattle and that their geographic distribution in Kansas resembles that of histoplasmin reactors in human beings. Determination of the age-specific rates for cattle and men in a single county in Kansas makes it evident that the rates are quite similar in human beings and cattle of like age. From this it is deduced that both cattle and men are probably infected from the same outside source and that cattle do not constitute an animal reservoir of importance in the spread of the disease to human beings.

AFTER we began preparing coccidioidin from asparagine synthetic medium [1] and distributing it on request, reports received indicated that the material was specific and that the coccidioidal endemic area of the United States was confined to the arid Southwest. The first seriously discordant note was the experience of Furcolow and Nelson in an orphanage in Ohio [2] wherein a considerable number of reactors were discovered. They found few reactors with dilute coccidioidin but a large number with concentrated material. Their findings made us suspect some unrecognized form of cross-reaction, for in our experience in coccidioidin surveys [1] most reactors are detected with the more dilute (1:1,000) material and only 10 per cent more are detected with a 1:100 dilution. However, until 1941 when we began our systematic coccidioidin surveys in the San Joaquin Valley Army Air Fields,[3, 4] we had observed no difficulties in interpreting the tests. Then we soon realized that either our coccidioidin did evoke cross-reactions or the endemic area extended into the central United States.

A number of equivocal and occasionally definitely positive coccidioidin

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

These investigations are an activity of the Commission on Acute Respiratory Diseases, Army Epidemiological Board, Office of the Surgeon General, Department of the Army. The study of coccidioidomycosis has been carried out at the Department of Public Health and Preventive Medicine, Stanford University School of Medicine, San Francisco, Calif.

reactions were discovered among groups of soldiers who had never before been west of the Rockies. In most instances the skin tests were performed too soon to have permitted locally acquired coccidioidal infection. With the enthusiastic coöperation characteristic of the commissioned and non-commissioned officers at those air fields, the new personnel would even be marched past us for their initial skin tests as they detrained, yet unexplainably equivocal and positive reactions would be elicited. The discovery by Emmons of *Haplosporangium parvum* in Arizona and the cross-reaction of haplosporangin and coccidioidin [5] added to our suspicion that an infection by another fungus might be responsible for these unexplainable reactions to coccidioidin. Indeed, in 1943 we prepared haplosporangin and discovered that these soldiers with equivocal coccidioidin tests frequently reacted vigorously to haplosporangin. However, many others did not react and it was evident that other agents must have been responsible for the nonspecific coccidioidin reactions.

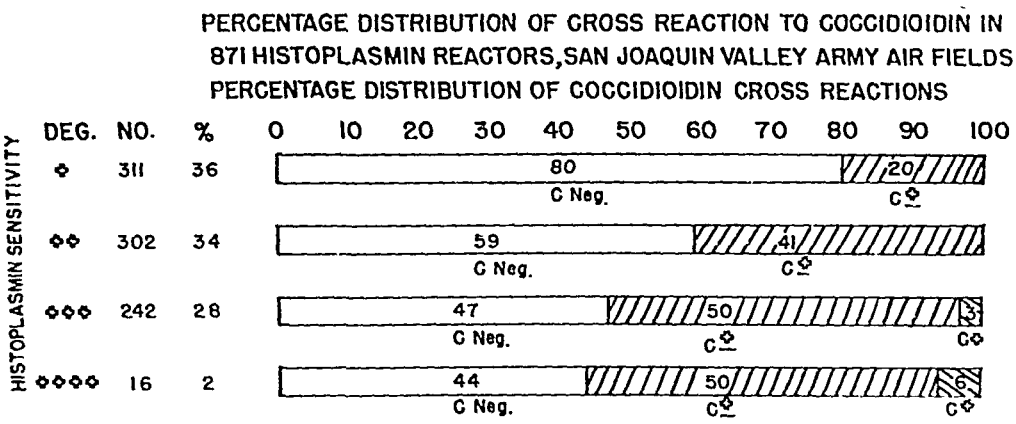
In casting about for another possibility we were reminded that in 1940 when we were first experimenting with serological tests for coccidioidal infection, we prepared an antigen from *Histoplasma capsulatum* which fixed complement in a patient with coccidioidal granuloma to the same high titer as did antigen made from *Coccidioides*. This same histoplasmin was used for skin testing by Aronson in his very significant Arizona survey of non-tuberculous pulmonary calcifications and was reported by him as evoking reactions.[6] The home states of the equivocal reactors to coccidioidin coincided with those central states having high frequency of pulmonary calcifications in non-reactors to tuberculin. The fact that we [7] had noted calcifications in coccidioidal lesions, evidence greatly extended by Aronson's association of Arizonon pulmonary calcifications with coccidioidin sensitivity, caused us to suspect the rôle of some other fungus in the central states. Meleney's review [8] brought to notice the fact that histoplasmosis was most frequently reported from the same area.

The parallel between histoplasmosis and coccidioidomycosis was already strong. Rixford and Gilchrist [9] believed *Coccidioides immitis* was an animal parasite, as Darling [10] deemed *Histoplasma capsulatum*. Then as Ophüls and Moffitt [11] demonstrated that the former is a fungus, da Rocha-Lima [12] suspected and De Monbreun [13] proved that *Histoplasma* is also a fungus. All that would be needed to complete the analogy would be to demonstrate a benign form of histoplasmosis, as Gifford [14] and Dickson [15] showed with coccidioidal erythema nodosum. Accordingly in 1943, we [16] called attention to the problem of interpreting coccidioidin reactions in individuals from the Ohio River basin and contiguous areas, and the possible association of these bizarre reactions with histoplasmosis and pulmonary calcifications. These suggestions were only conjectures and certainly do not detract from the brilliant discoveries of those who have been associating pulmonary calcifications with sensitivity to histoplasmin. Our subsequent investigations with histoplasmin have not dealt with pulmonary calcifications but with the relationship to coccidioidin sensitivity.

Christie's investigations at Vanderbilt University, Nashville, Tenn., of pulmonary calcifications in those not reacting to tuberculin, convinced him that neither coccidioidal nor haplosporangial infections were responsible. He turned to *Histoplasma* and in 1944 sent us histoplasmin prepared on beef-broth medium by himself and Peterson. We shall refer to it as Vanderbilt histoplasmin, which is the same material used by Christie and Peterson in their studies of pulmonary calcifications.[17–20] Using

Vanderbilt histoplasmin in 1:100 dilution, we tested a number of our "equivocal" coccidioidin reactors and invariably they were strongly positive. We kept the histoplasmin on hand for tests when an interpretation of coccidioidin reactions was difficult, but not until the next year did we use it systematically.

As the Christie-Peterson discoveries progressed, we realized that we should include a histoplasmin test with our routine coccidioidin test, and in the spring of 1945 we began this simultaneous testing. With the publication of Palmer's [21, 22] momentous papers associating pulmonary calcifications with sensitivity to histoplasmin in nurses, we sought a supply of the same histoplasmin, which he secured from Emmons of the National Institute of Health. It should be emphasized that neither Emmons nor his associate Salvin at the N.I.H. distribute histoplasmin, nor do Christie and Peterson any longer. Emmons very kindly made an exception for us and sent us some of his Lot 3 histoplasmin, which was grown on asparagine synthetic media comparable to that used for tuberculin and coccidioidin.[23] This histoplasmin will be referred to hereafter as N.I.H. histoplasmin. Although Emmons suggested the same 1:1,000 dilution which Palmer had used, we first tried the N.I.H. histoplasmin in the 1:100 dilution we were using for the Vanderbilt histoplasmin and our coccidioidin. However, it frequently evoked stronger reactions in those known to be undergoing coccidioidal infections than we elicited from our coccidioidin. When we used the N.I.H. material in 1:1,000 dilution, it compared very closely with Vanderbilt 1:100 histoplasmin as we shall show later in more detail.



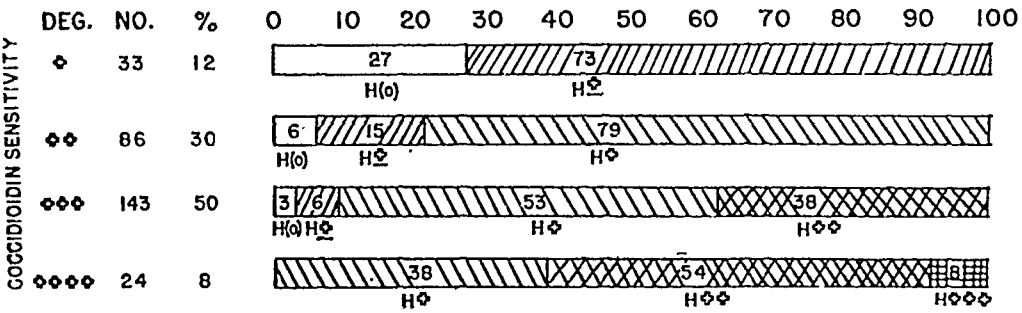
The coccidioidin was a 1:100 dilution of Lot 9, the same lot used throughout our Army studies. The coccidioidin and histoplasmin were injected at the same visit in the usual 0.1 ml. dosage intradermally in the volar surface of the left forearm, the histoplasmin proximally and the coccidioidin distally. The description of our testing and retesting procedures is presented in detail elsewhere.[3] Except at retests when all non-reactors to coccidioidin were being rechecked, one person did all of the testing and reading. At the time of retests, another of the investigators would also test or interpret, but the permanent tester was working alongside. Thus uniformity in techniques and interpretations was assured. Readings were made at 24 or 48 hours and were the generally accepted ones. Redness without induration of 5 mm. or more, or induration less than 5 mm. in diameter were considered equivocal and recorded as plus-minus (±). Induration of 5 to 9 mm. was recorded as one-plus (+). Induration of 10 to 14 mm. was recorded as two-plus (++) and of 15 mm. and more as three-plus (+++). When necrosis occurred, the reaction was recorded as four-plus (++++).

CROSS-REACTIONS OF COCCIDIOIDIN IN DOMINANT REACTORS TO HISTOPLASMIN

Out of 3,376 simultaneous histoplasmin tests in coccidioidin non-reactors or equivocal reactors, 864 (25.6 per cent) of the histoplasmin tests were positive. There were 7 others with one-plus coccidioidin reactions whose large histoplasmin tests placed them in the group dominantly sensitive to histoplasmin. It was in this group of 871 histoplasmin reactors that the vexatious equivocal and unexplainable positive coccidioidin tests were seen.

Figure 1 indicates the association between the degree of dominant histoplasmin sensitivity and these cross-reactions of coccidioidin. As we shall see later, there was no significant difference between histoplasmin tests using N.I.H. 1:1,000 histoplasmin or Vanderbilt 1:100 histoplasmin, so Figure

FIGURE 1



1 combines the two. We note that with one-plus histoplasmin reactions, 20 per cent of the coccidioidin reactions were equivocal. With two-plus histoplasmin reactions the proportion of equivocal coccidioidin reactions doubled. The three- and four-plus histoplasmin reaction were accompanied by a still higher proportion of coccidioidin cross-reactions, with 7 actually positive (one-plus) coccidioidin reactions. These positive coccidioidin reactions were in recent arrivals to the coccidioidal endemic area who had normal sedimentation rates and negative coccidioidal serological tests, evidence against any current coccidioidal infection. The greater the sensitivity to histoplasmin, the larger was the proportion of non-specific cross-reactions to coccidioidin. However, even with three- and four-plus histoplasmin reactions, approximately half the simultaneous coccidioidin tests were entirely negative. Thus, coccidioidin did not cross-react to a degree which interfered with interpretation. This is in accordance with the experience of Christie and Peterson,[17] Palmer,[21] Emmons, Olson, and Eldridge,[23] and Howell's animal studies.[24] However, when the coccidioidin concentration was increased to 1:10, nearly all " equivocal " reactions became definitely positive. For example, a trial of 1:10 coccidioidin in 12 histoplasmin reactors equivocal (±) to 1:100 coccidioidin resulted in 10 unquestionably positive reactions. When Furcolow and Nelson [2] in their Ohio orphanage increased the coccidioidin concentration, the proportion of reactions rose from 1 per cent with 1:1,000 coccidioidin to 50 per cent with 1:10. As we have recently pointed out,[25] in some patients with coccidioidal pulmonary cavitation it is necessary to go up to 1:10 coccidioidin to evoke a reaction. Patients with disseminated coccidioidal infections (coccidioidal granuloma) frequently have very poor sensitivity to coccidioidin, which is of some prognostic value.[1]

Such testing with coccidioidin may bring one to concentrations in which cross-reactions to dominant histoplasmin sensitivity pose a vexatious problem. However, we who are concerned with coccidioidal infections are relatively fortunate in that coccidioidin appears to be much more " specific " than histoplasmin. As Groover, *et al.*[26] observed in their patients with pulmonary disease, " Patients with a strong reaction to histoplasmin in a 1 to 1,000 dilution usually showed a mild reaction to coccidioidin in 1 to 10 dilution; those with a strong reaction to coccidioidin in the 1 to 1,000 usually had a mild reaction to the 1 to 1,000 dilution of histoplasmin." Thus, only if the coccidioidin was used in a concentration 10 times that advised for

FIGURE 2

SAN JOAQUIN VALLEY ARMY AIR FIELDS
PERCENTAGE DISTRIBUTION OF HISTOPLASMIN CROSS REACTION

routine tests, did cross-reactions in dominant histoplasmin reactors result. On the other hand, histoplasmin in its accepted concentration produced cross-reactions in those dominantly sensitive to coccidioidin. It is this cross-reaction which we shall consider next.

CROSS-REACTIONS OF HISTOPLASMIN IN DOMINANT REACTORS TO COCCIDIOIDIN

The investigation of cross-reactions of histoplasmin in dominant reactors to coccidioidin dealt with smaller numbers because once detected, coccidioidin reactors were not retested routinely. In Figure 2 are presented the histoplasmin reactions of 286 dominant coccidioidin reactors who received simultaneous histoplasmin and coccidioidin tests in the Army Air Force studies. One hundred and forty-six were tested in routine surveys and 140 were undergoing actual coccidioidal infections at the time of the tests. There was no significant difference in the relative reactions within the two groups, so that they are combined for presentation. One notes that, as coccidioidin sensitivity increased, the cross-reactions with histoplasmin became greater in degree as well as in proportion. While 27 per cent of the 33 one-plus coccidioidin reactors did not react at all to histoplasmin, each of the 24 four-plus cocidioidin reactors also reacted to histoplasmin, over half with a two-plus response. Over nine-tenths of the histoplasmin tests in coccidioidin reactors were positive, with nearly two-fifths showing at least two-plus reactions.

Of course, one asks if these reactions to histoplasmin might not have been the results of independently acquired sensitivity to histoplasmin. In most instances this possibility could not be excluded. However, we had a group of 31 who failed to react both to histoplasmin and to coccidioidin and subsequently acquired coccidioidal infections. Twenty-four were Army personnel and 7 were Stanford Medical School personnel who underwent laboratory infections. Eighteen of the former and 5 of the latter had definite symptoms, while 6 of the Army and 2 of the laboratory infections were inapparent. In 19 of the Army and all 5 of the laboratory infections which were clinically manifest, we obtained serological evidence of infection, as well as "conversion" of the coccidioidin test. As we see in Table 1, the smallest coccidioidin reactions were over 10 mm. in diameter and in the 9 recorded as two-plus, each had developed one-plus sensitivity when tested with histoplasmin. Of the 15 three-plus coccidioidin reactors, 9 (60 per cent) gave

TABLE 1

Dominant Coccidioidin Reactions and Histoplasmin Cross-Reactions in 31 Persons Originally Negative to Coccidioidin and Histoplasmin Who Subsequently Acquired Coccidioidal Infections

Degree of Sensitivity to Histoplasmin	Degree of Sensitivity to Coccidioidin			
	C++	C+++	C++++	Total
H+	9	9	2	20
H++	0	6	5	11
Total	9	15	7	31

one-plus reactions to histoplasmin and 6 were two-plus. There were 7 four-plus reactors to coccidioidin, 2 giving one-plus reactions to histoplasmin and 5 having two-plus reactions. Thus we observe this same pattern, the patients with greatest sensitivity to coccidioidin having developed greatest sensitivity to histoplasmin. The preceding negative histoplasmin test eliminated the possibility of a dual infection having been responsible for the cross-reaction.

These cross-reactions of histoplasmin in coccidioidal infection substantiate the belief that histoplasmin sensitivity is acquired by actual infection. Also, they could support the possibility that fungi other than *Histoplasma* might be responsible for the histoplasmin sensitivity. However, such fungi still would have to fulfil the requirement of marked restriction in geographic distribution.

BLASTOMYCIN REACTIONS IN COCCIDIOIDAL INFECTIONS

Emmons's[23] clinical studies at St. Elizabeths Hospital indicated cross-reactions between histoplasmin and blastomycin. Moreover, experimental infections of laboratory animals with *Histoplasma capsulatum* and *Blastomyces dermatitidis*[23, 24] have demonstrated a large proportion of cross-reactions. Howell's[24] studies indicated that by serial dilutions, the homologous skin testing material became differential. Bunnell and Furcolow,[27] by using Howell's method of serial dilutions, concluded that, in their patient infected by *Histoplasma capsulatum* who also reacted to blastomycin, the histoplasmin sensitivity was dominant.

We made no attempt to compare sensitivity of blastomycin and histoplasmin in dominant histoplasmin reactors. However, we did make a small study of blastomycin reactions in patients who were undergoing coccidioidal infections.

Donald Martin of Duke University kindly supplied us with skin testing "vaccine" of yeast phase *Blastomyces*. In 18 patients undergoing clinical coccidioidal infections, we performed simultaneous tests with 1:100 coccidioidin, 1:1,000 histoplasmin and this blastomycin. As Table 2 shows, the nonspecific

TABLE 2

Histoplasmin and Blastomycin Cross-Reactions in 18 Patients Undergoing Clinical Coccidioidal Infections Arranged According to Coccidioidin Sensitivity

Degree of Histoplasmin and Blastomycin Sensitivity		Degree of Coccidioidin Sensitivity

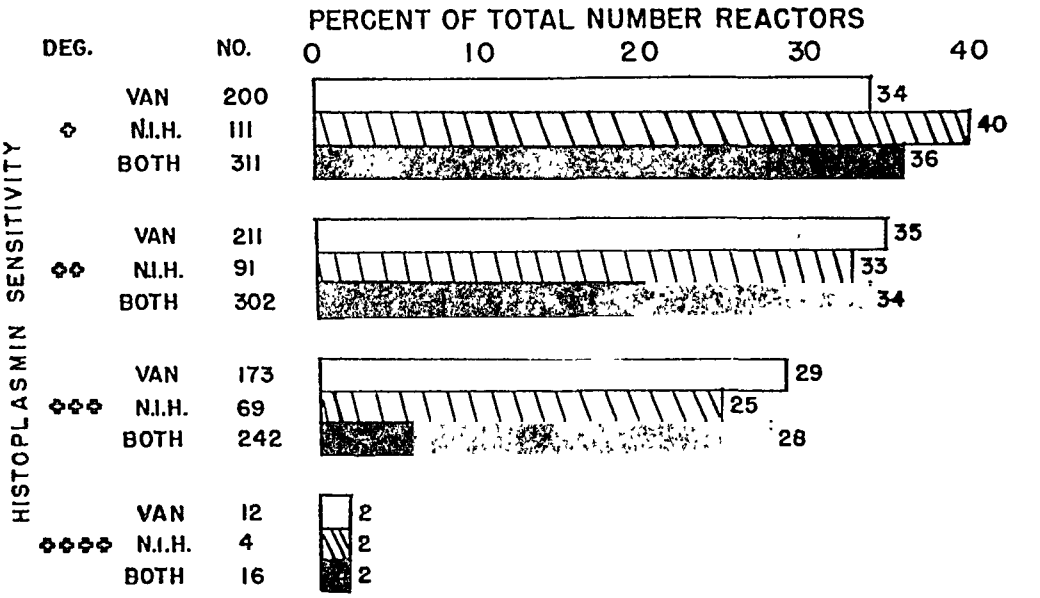
H±	B±	3	1	0	4
H±	B+	0	1	1	2
H+	B±	0	1	0	1
H+	B+	0	4	5	9
H+	B++	0	0	1	1
H++	B++	0	0	1	1
Total		3	7	8	18



cross-reactions by the two latter antigens were almost identical. Thus, in this small group there was indication that the cross-reaction of histoplasmin elicited by coccidioidal infection is shared by yeast phase blastomycin.

SIZE OF HISTOPLASMIN REACTIONS—COMPARISON OF VANDERBILT AND N.I.H. HISTOPLASMIN

Figure 3 presents the distribution of size of reactions in dominant reactors to histoplasmin. We note that slightly more than one-third were one-plus, one-third were two-plus, between one-quarter and one-third were three-plus, and only 1 in 50 was four-plus. The concordance between Vanderbilt 1:100 histoplasmin

and the N.I.H. 1:1,000 histoplasmin was very close.

Further comparisons of the N.I.H. and Vanderbilt histoplasmins gave additional evidence of their comparability in the dilutions used. For instance, the overall percentage of histoplasmin reactors in 1,950 persons negative or equivocal to coccidioidin tested with the Vanderbilt material was 26.1. Of the 1,426 tested with N.I.H. histoplasmin, 24.8 per cent reacted. At Minter Field 230 coccidioidin-negative or equivocally reacting personnel tested between July and November, 1945, with Vanderbilt histoplasmin were retested with N.I.H. material in January, 1946. One hundred and sixty-two were negative both times and 3 were equivocal both times. Of the 65 positives, 3 giving one-plus reactions to N.I.H. histoplasmin had been negative (1) or equivocal (2) to Vanderbilt material, but these were balanced by 2 who had one-plus reactions to Vanderbilt histoplasmin and who were negative (1) or equivocal (1) to N.I.H. histoplasmin. Thirty-two histoplasmin-positive reactions were recorded as the same in both tests. In 27 they differed by a single "plus" (15 being stronger with the N.I.H. material and 12 with the Vanderbilt). In only 1 instance did they differ by two "plus" (one-plus Vanderbilt and three-plus N.I.H.). Allowing for unavoidable variations in techniques of injections, these results appear quite uniform. Moreover, in the 2 to 6 months elapsing between tests, there was no evidence of loss of sensitivity.

The question also arises as to comparative specificity of the histoplasmins. There was no evidence that the Vander-

bilt material on beef broth gave gross nonspecific reactions as compared with the N.I.H. material in synthetic medium. The question really centers on the matter of cross-reactions in the dominant coccidioidin reactors. In 52 patients undergoing active coccidioidal infections, simultaneous tests were performed with 1:100 coccidioidin, 1:100 Vanderbilt and 1:1,000 N.I.H. histoplasmin. The two histoplasmins gave the same reactions in 34 cases. In 6 instances, one was equivocal and the other one-plus (Vanderbilt histoplasmin giving the larger reaction once and N.I.H. 5 times). In 12 patients the difference was by one "plus," with N.I.H. giving stronger reactions 8 times and Vanderbilt 4 times. In no test was there a difference of more than a single "plus." Thus, the cross-reactions did not differ significantly between the two materials.

As these comparisons were made prior to the production of histoplasmin either by Howell for the Division of Tuberculosis Control of the U. S. Public Health Service or by the Eli Lilly Company, we cannot compare the two materials now being distributed most widely. However, it is apparent that one should know his material and use it in accordance with its accompanying directions.

DURATION OF HISTOPLASMIN SENSITIVITY

Allusion has already been made to the the retest of 65 reactors to histoplasmin after an interval of 2 to 6 months and the fact that sensitivity had persisted. Olsen, Bell, and Emmons [28] mention a 7 per cent reversion from positive to negative out of 57 reactors retested after an interval of 3 to 8 months. The time intervals and numbers in both groups are very small. We were able to observe maintenance of histoplasmin sensitivity long after half a dozen reactors had taken up residence in California, an area relatively free of the agent or agents producing dominant histoplasmin sensitivity. One Army reactor after 9 years in Ohio had lived 10 years in California. Another, after 14 years in Oklahoma, had been 10 years in California. A third, after 17 years in Indiana, had resided 12 years in California. A fourth, after 18 years in Ohio, had lived 27 years in California. In tests of persons at Stanford Medical School, we discovered 2 other reactors who had been in California continuously for 21 and 24 years after coming from the Middle West (Kansas and Missouri and Illinois). These additional observations certainly indicate that histoplasmin sensitivity may persist for long periods, its durability apparently resembling that shown for tuberculin and coccidioidin.[1]

GEOGRAPHIC DISTRIBUTION OF DOMINANT HISTOPLASMIN SENSITIVITY

Early in the war a large proportion of the personnel of the San Joaquin Valley Army Air Fields was recruited locally. However, by 1945 when the histoplasmin was used routinely with coccidioidin, transfers had shuffled the personnel so effectively that we had a fair representation from most of the United States. This fact permitted us to study the geographical distribution of dominant histoplasmin sensitivity. All of these 3,376 histoplasmin tests were in adults. Two hundred and three were in women, 306 were in Negro males, and 2,767 in white males. The place where sensitization to histoplasmin was presumed to have been acquired was ascertained by asking for the "home state" and "home county." Our rosters also carried beside each name the state of birth. When the soldier's home state and state of birth did not coincide, he was asked further questions as to his residence. If he had lived in a number of states, no attempt was made to tabulate a state for him. Also, if his histoplasmin was positive and he had spent over 3 months in a central state or the Panama Canal Zone, no allocation was made. In our own experience very

transient exposures have sufficed to provide coccidioidal infections. Mere automobile or train travel through an endemic area has resulted in infection. Therefore, we felt justified in not "crediting" histoplasmin sensitization to a "home state" where native sons who had been in constant residence

(Map reproduced by courtesy of Rand McNally & Co., Chicago)

FIGURE 4—Percentage of Histoplasmin Reactors among Army Air Force Personnel Classified by States of Residence

showed no sensitivity while the few reactors had definite histories of residence elsewhere in areas with a high proportion of positive histoplasmins. The failure to allocate these reactors results in a somewhat lower percentage of reactions in the group in which allocation by states was made than in our overall tests. Of the 3,376 tested, 25.6 per cent reacted to histoplasmin. Of the 3,264 (111 fewer) in whom the allocation could be made to states, 24.1 per cent were reactors.

In Figure 4 we see the geographical distribution of dominant histoplasmin sensitivity by states. The numerical presentation in Table 3 also tabulates the findings of two other published surveys, that of Palmer's group of nurses [22] and that of Christie and Peterson's college group at Vanderbilt University.[18] The table also indicates certain published local surveys.[29-33] The surveys by Palmer and by Christie and Peterson agreed with ours in broad aspects. Table 4, presenting the states in order of their proportion of positives, emphasizes this agreement very strongly. Two other large "local" surveys also agreed closely. The Kansas City study by Furcolow, *et al.*[30] had 79 per cent reactors compared with our 82 per cent and Palmer's 80 per cent for Missouri. Prior and Allen's life-time Ohio residents (university and nursing students) [31] had 47 per cent reactors compared to our 45 per cent while Palmer's were somewhat higher, 60 per cent. In general, the states of the Missouri, Mississippi, Ohio, and Tennessee valleys had maximal incidence. The New England states and the Pacific Coast and Rocky Mountain states were free. Texas was notable, in that dominant histoplasmin sensitivity

was confined to the east and center, with its arid west and south, areas of coccidioidal endemicity, providing no dominant histoplasmin sensitivity. Our other attempts at allocation by counties were not revealing, as numbers were too small. We could not develop any significant figures for Arizona, for practically all of those claiming Arizona as their home reacted dominantly to coccidioidin. As we have seen, the histoplasmin cross-reactions in persons who have undergone coccidioidal infections are frequent. Doubtless this fact accounts for our major discrepancy with Palmer's findings, where he had 6 per cent reactors in Californian nurses. Moreover, his state breakdown gave Area II in the central section of California, which included a considerable amount of the coccidioidal endemic area, as 17.6 per cent reactors, compared with the low of 3 per cent in the northern part of California outside the coccidioidal endemic area.

The freedom of the Pacific Coast and Mountain states from dominant histoplasmin sensitivity is also supported by the absence of cases of histoplasmosis acquired in California. It is true that 2 cases of histoplasmosis have been reported from California. Tissue sections from the first reported case were thought to be Leishman-Donovan bodies but when they were sent to Meleney, he identified them as *Histoplasma*. The history as given by Crumrine and Kessel [34] stated that the patient was a Negro male who lived in the back country of Louisiana and worked in saw mills in Texas, moving to the Los Angeles area of California in the spring of 1927. The onset of his fatal illness was given as approximately October of 1927. Incidentally, his pulmonary x-rays showed

scattered calcifications. The second case was listed by Meleney [8] and reported by Martin and Silber.[35] We are indebted to Meleney [36] for the information that this patient was born in Tennessee and had been in the Los Angeles area 4 years before death. As she was a diabetic, alcoholic and morphine addict, and had had staphylococcal abcesses in various parts of her body several years before her final illness, the duration of her histoplasmosis would seem uncertain. Indeed, Meleney in writing us mentioned that he had just reviewed the sections of the adrenal where organisms had been noted and found an area of calcification therein which had been overlooked previously. He commented: ". . . the calcification is interesting in connection with the recent developments in histoplasma infections."

We recovered *Histoplasma* from a sinus tract on the thorax of a veteran in a California veterans' hospital, but he had come from Arkansas. Another patient from whose buccal lesions Johnstone recovered *Histoplasma* at the University of California Hospital [37] had lived in the central states. With physicians, and especially pathologists, conditioned by coccidioidomycosis to be on the alert for mycotic infections, it seems unlikely that any significant amount of fatal but undetected histoplasmosis would be occurring in California. The fact that a few cases of histoplasmosis have been detected, all traceable to the central states, is further evidence against failures of diagnosis. It would clarify matters if future tabulators of the geographical distribution of reported cases of histoplasmosis would at least indicate the possibility that the cases reported from California were acquired in the central United States.

The freedom of the New England area was commented on by Parsons and Zarafonetis [38] in their 1945 review of 71 cases of histoplasmosis. Noting that over half of these cases had been reported from states lying along the Mississippi River and its main tributaries (Michigan being the sole exception), they added: "We are unable to attribute definite significance to the facts or fact that *no* cases have been reported from the New England states." The same aspects of geographic localization of histoplasmosis in the United States have been borne out by more recent reviews of reported cases.[39, 40]

A small number of soldiers, 17 in all, had been born in Europe and spent some years there. All were histoplasmin-negative. One member of the Women's Army Corps from Puerto Rico was positive. Five histoplasmin reactors with home states (California, Connecticut, Idaho, Maine, Washington) outside the histoplasmin endemic area of the continental United States and without residence or service in it, had two or more years of Army service in Panama. One naturally recalls that the site of Darling's discoveries was Panama and that recently Tomlinson and Grocott reported the recovery of *Histoplasma* from a dog of the Canal Zone.[41] Two years ago a 7 year old child was examined for admission to Stanford Convalescent Home. A lesion in his pulmonary roentgenogram was thought to be a primary tuberculous focus, but his Mantoux test was negative. His histoplasmin was four-plus. His entire 2 years' residence in the United States was in San Francisco, and he had come directly from San Salvador where he had been born.[42] Certainly, Central America would seem to offer excellent opportunities for the study of histoplasmin sensitivity and pulmonary calcifications in non-reactors to tuberculin.

Admittedly, distribution of histoplasmin sensitivity is not proved to be the exclusive result of infection by *Histoplasma capsulatum*. The published [17–20] and unpublished [43] studies by Christie, Peterson, and McVicars at Vanderbilt, and the reports by Bunnell and Fur-

colow[27] do provide evidence increasingly incriminating *Histoplasma* as one very important element. While Groover, *et al.*[26] reported inability to demonstrate *Histoplasma* in bone marrow, sputum or lymph nodes of 7 strong reactors to histoplasmin, negative to cocidiodin and tuberculin, such recoveries would not have been anticipated. Comparable coccidioidin reactors, even with residual pulmonary lesions, would not have *Coccidioides* recoverable by similar procedures unless they had pulmonary cavities. The critical studies of Emmons, Olson, Bell, and their associates,[23, 28] while indicating the potential usefulness of histoplasmin, have emphasized the necessity of its careful evaluation, especially with respect to association with pulmonary calcification. In this regard it is noteworthy that one-third of the 102 Ohio children with pulmonary calcifications studied by Sontag and Allen[32] reacted neither to histoplasmin nor to tuberculin.

Certainly, the geographic distribution of histoplasmin sensitivity indicates the presence of a specific cause or causes, themselves occurring in restricted areas. Sensitization by a widespread fungus like *Candida albicans*[44] or by penicillin,[26] while theoretically possible because of cross-reactions which have been demonstrated, does not offer a very plausible explanation since geographic localization would be unexplained. However, the fact that histoplasmin reacts so frequently in coccidioidal infections and that there is such marked cross-reaction with experimental blastomycosis indicates the possibility of sundry mycotic infections.

Recently W. L. Potts, Medical Director of Franklin County (Ohio) Tuberculosis Hospital[45] informed us of 3 patients who had never left Ohio and who reacted to coccidioidin but not to histoplasmin. Knowing that *Coccidioides* does not occur naturally in Ohio, we must assume either exotic coccidioidal infections or the existence of another mycotic infection which, at least occasionally, evokes cross-reactions to coccidioidin. Certainly it is theoretically possible for other mycoses to produce infections with cross-reactions to histoplasmin. However, if histoplasmin sensitivity is the result of infections by several agents, these infections must still be restricted in distribution to account for the geographical distribution of histoplasmin sensitivity. Moreover, while the infection spectrum[4] of coccidioidal infections indicates that 60 per cent are completely inapparent, the infection or infections responsible for histoplasmin sensitivity are even less manifest.

Thus far, despite diligent searches, the etiology of the only reported clinically apparent infections associated with dominant histoplasmin sensitivity have been by *Histoplasma*.[20, 27] The search must continue and, in the meantime, assumption that histoplasmin sensitivity proves an infection by *Histoplasma* is uncritical. Fortunately, from a diagnostic point of view, coccidioidin has proved much more specific, though, as we have seen, it has its definite limitations when used singly. A "battery" of several skin testing agents used at their appropriate "critical titers"[24] may be advisable, although every attempt should be directed to obtaining purified and specific material.

SUMMARY

Simultaneous coccidioidin and histoplasmin skin tests were performed on normal military personnel and others undergoing coccidioidal infections using 1:100 coccidioidin and either 1:100 histoplasmin from Christie and Peterson (Vanderbilt University) or 1:1,000 histoplasmin from Emmons (National Institute of Health). Among 3,376 healthy persons negative or equivocal to coccidioidin, 26 per cent reacted dominantly to histoplasmin. Equivocal and

occasionally positive coccidioidin reactions in individuals who had no opportunity of acquiring coccidioidal infections were found exclusively in the group of histoplasmin reactors. The stronger the histoplasmin sensitivity, the more frequent and larger the nonspecific reactions to coccidiodin. The nonspecific coccidioidin reactions were not so great as to interfere with interpretation, especially when interpreted in the light of the reaction to appropriate dilution of histoplasmin. However, if strong (1:10) coccidioidin was used as it must in some forms of coccidioidal infections, the hazard of a positive nonspecific reaction was considerable.

The histoplasmin test in dominant coccidioidin reactors showed a much higher degree of cross-reaction In 31 persons negative both to coccidioidin and histoplasmin, subsequent coccidioidal infections evoked sensitivity and concomitantly positive histoplasmin as well as coccidioidin reactions. Simultaneous blastomycin, histoplasmin, and coccidioidin tests in patients undergoing coccidioidal infections showed nonspecific cross-reactions of the blastomycin and histoplasmin approximately to the same degree. Again, the greater the sensitivity to coccidioidin, the greater the frequency and the size of the cross-reaction. Comparisons between the two histoplasmins used showed no significant difference in specificity, but the 1:1,000 N.I.H. histoplasmin was equivalent to 1:100 Vanderbilt material. If the former was used in 1:100 dilution, it frequently evoked larger reactions in coccidioidal patients than did 1:100 coccidioidin.

The presence of histoplasmin sensitivity in 6 persons who had been outside the area of dominant histoplasmin sensitivity for 10 years, with 3 longer than 20 years, bespoke its persistence.

The geographic distribution of dominant histoplasmin sensitivity disclosed reactions in four-fifths of those from Missouri, three-fourths from Tennessee and Kentucky, and concentric diminutions of positives until the New England, Rocky Mountain, and Pacific Coast states appeared virtually devoid of reactors. This was in close agreement with other studies. It indicated extensive inapparent infection, probably by *Histoplasmin capsulatum*, with or without some additional fungus or fungi with which histoplasmin cross-reacts extensively.

Histoplasmin appears to have limitations due to its cross-reactions, but used in appropriate relative strength, it, and coccidioidin, are valuable in the diagnosis and epidemiological investigation of pulmonary lesions.

Isolation of the Virus of Newcastle Disease from Human Beings

W. L. INGALLS, D.V.M., AND ANN MAHONEY

Department of Veterinary Pathology, College of Veterinary Medicine, Ohio State University, Columbus, Ohio

NEWCASTLE disease (Avian Pneumoencephalitis) is one of the more recent diseases affecting poultry in the United States. In young birds it produces respiratory and nervous symptoms, whereas in older birds the symptoms are primarily of a respiratory nature. The causative agent is a filtrable virus which closely resembles human influenza virus A & B. (Burnet [1]).

In the United States the Virus has attacked primarily chickens and turkeys; however, all of the common barnyard fowls are susceptible. In 1947, Reagan and coworkers [2-4] showed that the virus was adaptable to certain mammals such as the Syrian hampster and Rhesus monkey by the intracerebral route. Mice, guinea pigs, and rabbits were relatively resistant.

The first report of this disease in fowls was by Kraneveld in the Dutch East Indies in 1926, and the following year Doyle reported the isolation of the causative agent at Newcastle-on-Tyne in England. Since that time it has spread over many countries throughout the world. Earliest reports on its occurrence in the United States were by Beach in California in 1941.

The disease as observed in the United States has differed from that encountered in other countries in that the mortality has been low in adult birds, whereas in other countries it has been almost 100 per cent.

Although much has been written about Newcastle disease in poultry, only six reports in literature mention its occurrence in human beings. Of this number only two mention the recovery of the virus. In 1943 Burnet [5] described a laboratory infection (conjunctivitis) due to the accidental entrance of live virus into the human eye. Anderson,[6] in 1946, reported two other laboratory infections of man in Australia. All patients showed a conjunctivitis, and Newcastle virus was recovered from the tears.

Shimkin,[7] in 1946, recorded a case of conjunctival hemorrhage in a worker at the Government Poultry Laboratory in the northern district of Palestine. While circumstantial evidence seemed to indicate Newcastle virus as the causative agent, virus isolation was not reported. During the same year a small epidemic of contact infection by Newcastle virus occurred in employees at the Agricultural School, Mikveh, Israel, where an outbreak was occurring in the poultry flock. The cases were confined mostly to women kitchen personnel.

Howitt [8] and coworkers reported on the presence of neutralizing antibodies of Newcastle disease virus in human sera in the United States. McGough,[9] in 1949, also reported the presence of Newcastle neutralizing antibodies in sera of human beings who had become ill following the ingestion of cooked chicken. However, as far as is known, no reports have been made of the recovery of Newcastle disease virus from any human infections in the United States. Since there is a marked differ-

ence in the disease as it occurs in the United States compared to other countries, it appeared desirable to offer the following reports of recovery of the virus from apparently infected human beings in Ohio.

A broiler plant operator, P. N., brought several chickens to the Poultry Diagnostic Laboratory, College of Veterinary Medicine, Ohio State University on October 19, 1948, for diagnostic purposes. The history and symptoms shown by the birds were indicative of Newcastle disease. This was confirmed by isolation of the virus and hemagglutination inhibition (H.I.) techniques. It was noticed that the flock owner had a definite conjunctivitis of the left eye. Upon questioning, he stated that the condition had been observed 3 days after the sickness was noticed in his flock and had been present for 3 days but was now apparently improving. Gross examination revealed edema of the lids, marked hyperemia of the scleral and conjunctival vessels, and a definite mucopurulent discharge. No general symptoms had been noted, and medical aid had not been employed.

METHODS OF VIRUS ISOLATION

With his permission, a sterile cotton swab was placed in the medial canthus of the affected eye; and the recovered exudate placed in 1 ml. of sterile nutrient broth and incubated at room temperature for approximately 30 minutes. The material was frozen at — 18° C. and held under this refrigeration for 7 days until fertile hen's eggs of the proper stage of incubation were available. The material was then thawed and treated with approximately 5,000 units each of penicillin and streptomycin and left at room temperature for 30 minutes. Three fertile hen's eggs incubated at 37° C. for 9 days were each inoculated into the allantoic cavity with 0.15 ml. of the supernatant fluid. The shell openings were sealed with paraffin and the eggs further incubated at 37° C. Each of the embryos was dead on the morning of the third day following inoculation. Material from the dead embryos transferred to blood agar medium failed to show bacterial growth. Using the methods recommended by the B.A.I.,[10] cell-free allantoic fluid from the dead embryos agglutinated fowl red cells; and agglutination was inhibited specifically by anti-Newcastle-disease virus immune serum.

Three fertile hen's eggs incubated at 37° C. for 9 days were each inoculated with the stock solution of the antibiotics. All embryos remained alive and active, and the mixture was considered to be free of the virus.

Using techniques recommended by the B.A.I.,[11] the titer of the virus as determined by egg embryo inoculations was found to be 10^{-7}. Serum neutralization tests were indicative of Newcastle virus.

Two susceptible cockerels (H.I.-negative) approximately 6 months old and one Newcastle vaccinated hen (H.I.-positive) were inoculated with the above virus. Four days later a very slight respiratory involvement (moist rales) was noted in the 2 negative cockerels, whereas the vaccinated bird revealed nothing. Blood drawn from these birds 10 days after their injection was strongly positive on H.I. tests in all 3 birds.

A blood sample from P. N. approximately 1 month after having the conjunctivitis revealed strongly positive H.I. titer. No neutralization tests were conducted on this sample.

Virus from the original isolation was sent to the Pathological Division of the Bureau of Animal Industry in Washington for final confirmation. Their report is shown in Table 1.

A junior veterinary student, R. M., autopsied 1 chicken having a history and symptoms suggestive of acute Newcastle disease on November 21, 1948, and 2 chickens with symptoms of acute

TABLE 1

	10^1	10^2	10^3	10^4	10^5	10^6	10^7	10^8	10^9
N. Virus					3/3	3/3	3/3	1/3

Normal Avian Serum					3/3	3/3	2/3	1/3	

Newcastle disease on November 22, 1948. The diagnoses on these cases were confirmed by isolation of the virus and H.I. techniques. On the evening of November 23, 1948, his wife called his attention to a redness and swelling of his right eye; however, the condition did not seem painful. The following day he placed bichloride of mercury ointment in the affected eye and attended classes. Gross examination at that time revealed edema of the lids and hyperemia of the scleral and conjunctival blood vessels. Dr. Maurice L. Zox of the Student Health Service, Ohio State University, who examined the eye. described the conjunctivitis as "a granular type involving the palpebral conjunctiva." A sterile swab was placed in the medial canthus of the eye and gently moved laterally along the lower lid; and this material was then placed in 1 ml. sterile nutrient broth, to which 5,000 units each of penicillin and streptomycin were added. The mixture was incubated at room temperature for 30 minutes and was injected into 4 fertile eggs which had been incubated at 37° C. for 9 days. Two embryos died on the third day following inoculation; and the allantoic material was reinoculated into 4 12 day old incubated eggs. Forty-eight hours later all embryos were dead and the allantoic fluid was harvested. Material from the dead embryos transferred to blood agar medium failed to show bacterial growth. Cell-free allantoic fluid from the dead embryos agglutinated fowl red cells, and agglutination was inhibited specifically by anti-Newcastle disease virus immune serum.

The titer of the virus isolated, as determined by egg inoculation, was 10^{-8}, and serum neutralization was indicative of Newcastle virus. Serum neutralization tests conducted by the Pathological Division of the Bureau of Animal Industry on virus from the original isolation confirmed our diagnosis of Newcastle virus and gave the following results (Table 2).

TABLE 2

	10^1	10^2	10^3	10^4	10^5	10^6	10^7	10^8	10^9
N. Virus					3/3	3/3	3/3	3/3	1/3
Newcastle Disease Anti-serum	0/3	0/3	0/3	0/3					
Normal Avian Serum					3/3	3/3	3/3	3/3	1/3

The conjunctivitis persisted for 1 week in the student and gradually disappeared. No ill effects were noted other than a mild irritation which continued for 3 days after the onset.

SUMMARY

Two natural occurring cases of conjunctivitis thought to be due to the virus of Newcastle are reported. One case occurred in a broiler plant operator on whose premises Newcastle disease was in progress; and the second case was a veterinary student who, in the course of his clinical work, autopsied 3 chickens affected with acute cases of Newcastle disease. In the broiler plant operator, the virus identification was confirmed by hemagglutination, hemagglutination inhibition, serum neutralization techniques, and antibody response in chickens.

In the case of the student the virus identification was confirmed by hemagglutination, hemagglutination inhibition, and serum neutralization.

In addition to the above, virus sent to the Pathological Division, U. S.

Bureau of Animal Industry was identified as Newcastle virus.

This is believed to be the first reported case of the isolation of the virus of Newcastle disease from man in the United States.

Public Health Degrees 1947–1948

The January, 1949, issue of the *American Journal of Public Health* carried the Report on Public Health Degrees and Certificates which has been compiled by the Committee on Professional Education annually for the past 15 years As in previous years, the report on the academic year 1947–1948 contains valuable information on enrollment, the professional backgrounds of the students, the degrees offered and the degrees granted by the various universities Because of the special concern which the Engineering Section Project has had in training of engineers and sanitarians, the material this year is more complete than previously with respect to the postgraduate degrees in sanitary and public health engineering; in addition the findings of a special study on undergraduate students and degrees in engineering and sanitation are included. Two summary tables only were published in the January *Journal*. A set of 10 additional detailed tabulations in multilith form is available free on request from the office of the Association

Morbidity Surveys

The Morbidity Survey in Public Health Work *

GEORGE ST. J. PERROTT, F.A.P.H.A.

Chief, Public Health Methods Division, U. S. Public Health Service, Washington, D. C.

THE methods of measuring the characteristics, habits, and opinions of representative samples of our people have advanced rapidly in recent years. We have been learning to use what people have to say about themselves and their families, not only to satisfy the public's curiosity about itself but also to supply the needs of government and business planning and scientific research. It is natural, therefore, that we should be hearing more and more about plans to use the layman as an informant for acquiring data on morbidity in the general population. The idea is not new to public health people. In this country morbidity surveys based upon house-to-house canvasses date back to before the beginning of this century. But the supply of new information from this source is by no means keeping up with the demand. In the field of public health we are seriously hampered by lack of up-to-date and reliable figures on illness rates, the need for medical care, and the facilities for supplying it.

Certainly one of the reasons why the morbidity survey has not been used more frequently is the cost of this type of work, which is by no means trivial. Yet the amount of money required is no greater than is now spent to secure facts about the labor force or about livestock, or corn, wheat, and cotton crops. But when there is public recognition of this unbalanced state of affairs, shall we be ready with knowledge of how best to plan a survey—a survey that will combine what we have learned from past projects of this type with the new techniques of interviewing developed in the field of attitude research and with the rapid advances that have been made in population sampling methods? And do we know just what types of statistical data the health officer and epidemiologist most need? Have we, in fact, even convinced them that information on illness provided by these surveys is of value?

If we define a morbidity survey as it is ordinarily understood, as "any canvass of households or individuals for the purpose of collecting statistics on illness and closely related subjects, such as medical care and public health," that definition does not restrict the manner of selection of respondents nor the type of respondents to be used. They may be physicians asked about their patients, housewives asked about the members of their households, or individuals asked about themselves. In fact, the canvass may not involve an interview at all. It may depend instead upon the use of some diagnostic procedure, such as a physical examination, an x-ray, a blood test, or a blood-pressure reading. Whether this last type of investigation falls under the heading of a morbidity

* Excerpts from the remarks of the moderator in opening the Panel Discussion on Morbidity Surveys before a Joint Session of the Biometrics Section of the American Statistical Association, Biometrics Society, and the Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

survey, is open to some question, but it is certainly worth bearing in mind that this is the *only* type of canvass that will provide information on illness of which the individual himself is unaware.

Another sort of inquiry is that in which the information is secured from a physician, or from hospital or clinic records. This type may be very important, since in some situations nothing less than a professional opinion can be used. An example would be the cancer surveys of the sort carried out by the National Cancer Institute.

The three kinds of survey I have specifically mentioned correspond to three levels of awareness of illness. The diagnostic survey is the only one that can pick up illness of which the individual is unaware. The household survey or survey of individuals in the general population can only catch illness which the sick individual recognizes, but it can be made to cover unattended as well as attended cases. On the other hand, the doctor as an informant can only give information about illness that has been brought to his attention, that is, attended illness.

The topic of this panel discussion is restricted to morbidity surveys in which individuals are asked about their own health or the health of other members of their household, and which make use of diagnostic techniques and medical records only as validation or extension of the information obtained from such informants. This sort of survey has been singled out for discussion because it is the one which seems to hold out the most immediate hope for supplying us with additional estimates of the incidence and prevalence of illness which we so badly need.

Pre-Engineering Inventory

Recognizing the need for guidance to students about to enter college, the Engineers' Council for Professional Development has prepared a pamphlet, *Pre-Engineering Inventory,* to give advice to those students who may be contemplating the field of engineering. Discussion of this activity is contained in the 16th annual report of ECPD now being distributed. According to the report, 20,000 copies of *Pre-Engineering Inventory* have been distributed to various universities, high schools, preparatory schools, etc. A companion report, *Engineering as a Career,* found sales for another 20,000 copies during the year 1948–1949. The annual report summarizes the first year of accreditation following the disruption of the program during the war years. During the year 1947–1948, 40 institutions were visited where 125 curricula were reinspected and 46 were inspected for the first time for the purpose of accreditation. ECPD is located at 25 West 39th Street, New York 18.

Morbidity Surveys

Planning the Morbidity Survey *

THEODORE D. WOOLSEY, F.A.P.H.A.

Biostatistician, Division of Public Health Methods, U. S. Public Health Service, Washington, D. C.

IN planning the type of morbidity survey we are discussing this morning there are a number of decisions that have to be made. Each of these decisions is influenced by the particular purpose which the survey is to serve. Hence, it is first necessary to have that purpose clearly in mind. There should be one objective to which all others are secondary, and the survey should be designed with this major objective in view.

The preliminary decisions that have to be made can be grouped under three headings:

1. Defining the things we want to measure.

2. Defining the sample, including the units of sampling, the method of selection of the units, the method of estimating from the sample, and the sort of sampling error expected from this sampling plan.

3. Defining the interview, how it is to be conducted, who is to be considered an acceptable informant for the various persons in a household unit, who will do the interviewing and how the questions will be asked.

In this last category, also, we might place the decisions on the types of validation that we shall try to get; not only the validation of diagnostic and other information given us in the interview but also the tests of interviewer consistency and of the degree of understanding that exists between interviewer and informant. These are difficult things to tackle, but at our present stage of knowledge of morbidity survey techniques they are highly necessary.

In order that our sampling statisticians may design the best possible samples for us, we must supply them with as much information as possible about how morbidity rates vary. We are particularly short of statistics showing the geographical variation of morbidity. Such information is needed by the sampling man in order that he may determine whether it is necessary to spread the sample to many areas or whether it can be concentrated in a relatively few areas, thus cutting down the cost.

The sampling problems are by no means independent of the problems relating to definition of desired measures and design of interview. For example, if the primary interest is in measuring the amount of chronic disease in the population, we should prefer to visit a large number of households even if we visited each household only once. On the other hand, if our chief concern is with the acute communicable diseases, we shall do better to select fewer households and visit them repeatedly since we can obtain the same number of person-years of experience and more accurate information on date of onset

* Excerpts from remarks presented at a Joint Session of the Biometrics Section of the American Statistical Association, Biometrics Society, and the Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

and duration at a lower cost. Obviously, therefore, the matter of where the chief emphasis is to be placed affects the sample design.

In the Public Health Service we feel that we have now acquired a good deal of experience in working with the various measures of morbidity, incidence, prevalence, average duration, and the like. We have learned quite a lot about the interrelationships of disabling and non-disabling illness, bed illness, hospitalized illness, numbers of visits by doctors and nurses, classification of illness, and so on, and about the age-sex variation of these measures in specific communities. We have made the least progress in solving the problems relating to the interview itself. It is hard to frame objective questions to bring out illness that has not been attended by a doctor and has not been disabling in some specific manner, such as requiring the man to stay home from work or the child to stay home from school. Most serious chronic diseases that are recognized by the individual have at one time been attended by a doctor. If they had not been attended, then the individual usually would not know what he had anyway.

But what about the unattended, non-disabling illnesses? The individual is certain that he has been sick or is sick, but he has not seen a physician, and he still keeps on with his work. There is a lot of illness that comes under this heading. Surveys on the common cold alone prove that. Some of it is illness which *would* be attended under a system of prepaid medical care. Although some of it is minor, some of it may represent the unrecognized onset of a serious disease. The person may have been suffering from symptoms which he does not know how to diagnose himself and for which he has never yet consulted a physician nor taken any sick leave from his job. Are we to let this unattended and non-disabling illness go? If not, we are surely going to be involved in some intricate problems of attitude measurement, or something closely akin to attitude measurement.

Perhaps the health officer and epidemiologist will tell us that such illness is too ill-defined to be worth bothering about, but if it is determined to be part of what we want to measure, then we particularly need the help of the attitude research people to teach us how to frame our questions.

Life Insurance Medical Research Fund 1949 Grants

Early in March the Life Insurance Research Fund made grants totaling $585,000 to 35 universities and research centers in the United States and Canada for 53 different heart disease research projects. It also allocated $95,000 for the support of 18 graduate and 9 undergraduate research fellows who will work under the supervision of experienced investigators. One student will work in the Zurich, Switzerland, Pharmacological Institute.

The Research Fund at the same time announced the following additions to its professional advisory council:

Alfred Blalock, M.D., Johns Hopkins University

William S. Middleton, M.D., University of Wisconsin

Max M. Wintrobe, M.D., University of Utah

Morbidity Surveys

A Morbidity Survey of the Population *

NATHAN KEYFITZ

Mathematical Adviser, Dominion Bureau of Statistics, Ottawa, Canada

CERTAIN of the problems which arise in surveying morbidity are general; they are identical with those of surveys of the labor force, of blood types, of potato production. Other problems are specific to morbidity. Separation of these two groups has the advantage that we can bring to bear on investigations made by students of public health, experience gained in many other branches of statistical work. Since morbidity is not a field in which I have worked I can make a contribution, if at all, only in showing how the survey methods developed in other kinds of work may be applied in yours. I merely raise for your discussion one or two devices whose usefulness in other fields is now proved, and which have been brought into special prominence recently by the Sampling Sub-Commission of the United Nations.

Morbidity can be surveyed by asking questions of at least three different "units" — (a) households, (b) individuals, and (c) doctors. For any of these units a probability sample may be devised.

If households are the ultimate sampling unit they may be chosen at random among all the households of the country, or with some benefit in reduced variance, after division of the country into strata. This implies the existence of up-to-date lists for the whole country. If such lists are not available but good maps are to be had, one may choose certain large areas at first, then sample within these, etc., making the choice at random in each stage. Any sample which is to be visited should be concentrated in some fashion, so that the enumerators collectively will not have to travel over every part of the country; this method of concentrating it is known as area sampling and can be made unbiased so that every individual resident stands a known chance of inclusion. This was the type of sample used within cities in the pioneer effort of the National Health Survey in 1935–1936, conducted by the U. S. Public Health Service.

Some of the misunderstanding of the nature of sampling which has been prevalent during the past few years may have been cleared up by recent events. While it is often possible to select purposively those elements which seem most representative, or to obtain a sample by simply asking enumerators to fill quotas from among their friends or whoever else seems to them representative, yet any operation which proceeds in this manner involves very serious risk. If the man who designs the sample and oversees the tabulation has so close knowledge of the subjects that he can judge accurately what the population is like, it is indeed not necessary to have a probability sample. It happens, unfortunately, that one can never know whether the universe is as one thinks or different in respect of the subject of inquiry; this ignorance is why

* Excerpts from remarks presented at a Joint Session of the Biometrics Section of the American Statistical Association, Biometrics Society, and the Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

one samples at all. The Sampling Sub-Commission of the United Nations was very emphatic in its last session that quota methods cannot be relied on.

After we have in some way selected a set of areas, we are up against the fact that when we go to the individuals in them with a set of questions we will find that they have only a vague and approximate idea of their state of health and morbidity. We can of course do better than was done in a morbidity survey with which I was associated; as part of the Canadian National Registration of 1940 everyone was asked what was the state of his health, and he replied good, fair, or bad, with no definition of these terms. The tabulation reporting that there were 539,340 Canadians in bad health, etc., was not a major contribution. If we sample doctors instead, and work from their files, we may get more specific returns; but these are only for those people who have visited doctors, and it is not easy to avoid giving double weight to those who have visited two doctors, etc.

The question of accuracy of individual response can most efficiently be handled by selection of a subsample to constitute a second phase of the investigation. From the second phase respondents additional information is obtained which will enable corrections to be made on the first phase. This is the common sense principle which is involved in any proper conduct of a census, for example, where a check is made on the original enumeration by some kind of sample, and ideally even a further check is made on the sample by a subsample.

Thus, the initial area sample, clustered for accessibility, stratified at each stage for efficiency, would survey morbidity on such diagnosis of ailments as individuals, or their mothers, wives, etc., are capable of making. We may even suppose these are subject to so great an error of reporting that totals based upon them would be entirely useless. The returns as obtained from this survey may then be sorted according to the "folk" diagnoses which were received. A small sample, stratified according to these diagnoses, consisting of one household out of twenty (the sampling proportion perhaps varying with the stratum, i.e., the ailment), would be visited by a doctor or public health nurse. This official would ascertain which of the persons having arthritis, etc., in their own estimation had it in his. These would be subject to an addition for the number having arthritis according to medical diagnosis who did not themselves state it. The result of the second phase would be a series of ratios of numbers, e.g., of persons having arthritis on medical opinion to numbers of persons thinking they had arthritis, which would be available for correcting the results of the first sampling.

This is a device which can be used to secure accurate diagnosis and reasonably high sampling precision when very few doctors or nurses are available for the job. A nice mathematical problem —for a simple case of which a solution has been presented—is to specify how much enumeration is required in the first phase and how much in the second phase, when we know, as the result of a small pilot survey, the cost of enumerating in each phase, the accuracy of reporting in the first phase, and the accuracy required in the final result.

Morbidity Surveys

The Contribution of the Survey Method to Epidemiology *

ALEXANDER D. LANGMUIR, M.D., F.A.P.H.A.

Associate Professor of Epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md.

MY remarks will be confined largely to the simple morbidity surveys conducted by trained, but non-medical, investigators who interview a sample of the general population. More complex surveys, utilizing professional personnel or laboratory diagnostic techniques, I shall class as special studies.

I accept a broad definition of epidemiology as the science concerned with understanding the factors related to the occurrence and distribution of disease in the population. Epidemiology must consider both the sick and the well in their relation to each other and to their environment.

The morbidity survey is a particularly useful epidemiological tool in that data on both the sick and the well are obtained concurrently. The problems arising from underreporting of cases, from arbitrary classifications of causes of death, and from unknown shifts of population between census years are largely eliminated.

Morbidity surveys are of special value in the study of the acute respiratory group of diseases and the chronic illnesses, for which routine sources of data are grossly inadequate or nonexistent. The survey method, however, is not restricted to these two groups of diseases, but may be applied to many illnesses. Its unique advantage lies in the detailed information that can be collected about the population. Frequency rates, specific for a wide variety of social and environmental factors, can be determined. Such comparisons are not obtainable by matching routine morbidity reports and death certificates with census figures.

The simple morbidity survey has one inherent limitation—only general data about disease can be obtained. The questions asked by the interviewers must be simple and understandable to the informants. Few specific diseases can be adequately counted by this method. Special studies are necessary to collect such definitive epidemiological information.

Therefore, the simple morbidity survey must be restricted to the study of broad groups of disease. We can expect from such surveys measures giving only gross orders of magnitude for prevalence, seasonal variation, and for the degree of disability, and correlations giving only limited associations with the specific social and environmental factors we can measure for the sample population.

These crude observations may be most valuable. They form the stuff from which new ideas generate. They make possible the formulation of epidemiological hypotheses. They are most useful in designing special studies.

* Excerpts from remarks presented at a Joint Session of the Biometrics Section of the American Statistical Association, Biometrics Society, and the Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

In conducting morbidity surveys for epidemiological purposes, three points should be kept in mind:

1. The index for measuring the disease must be carefully chosen. The common striving to measure the total incidence of disease is a forlorn hope. Such an objective is contrary to the nature of disease itself. With rare exceptions, disease and health merge imperceptibly with each other. An index that is carefully defined and consistently followed is a first essential.

Indices vary in their usefulness. For example, it is of little value to learn that 10 per cent of a sample population said they had a cold last week. That is opinion. What is the definition of a "cold"? It is much more useful to learn that 3 per cent were in bed for one or more days with a cold last week. Such a figure is based on a definable index, understandable to the interviewer and to the informant alike. This index can be employed week after week in a consistent fashion. The results of one survey can be compared with another survey when such an index is used.

2. The choice of the sample population should be made with reference to the specific objectives of the study, rather than with the view to calculation of rates for the whole population. Such an extrapolation may be important in attempting to forecast an election or in estimating the overall need for medical care facilities. It has little basic value to epidemiology. To generalize from a sample implies an understanding of all the important factors influencing the occurrence of disease. If these were all known, there would be little epidemiological reason to conduct the survey. It is the function of epidemiology to elucidate the factors. Therefore, it is the internal comparisons within the sample that are important to epidemiology. The samples should be chosen to provide for the greatest differences in age, in crowding, in economic status, in environment, or whatever factors we wish to study. Such morbidity surveys provide the greatest opportunities for a better understanding of epidemiological problems.

3. Repeated surveys of the same individuals in the population provide more useful information than the single survey. The latter gives but a static measure at one moment. The former reveals the flow of disease through the community. It is from the study of these dynamic processes of disease that epidemiological understanding comes.

Through morbidity surveys, a small mountain of data can be collected with relative ease. Such data will be useful for epidemiological purposes if the questions asked be compatible with the inherent limitations of the method, if appropriate indices be selected for measuring disease, if the population sample studied be suitable to the questions involved, and if observations be maintained consistently and repeatedly over a period of time.

Morbidity Surveys

The Local Health Officer and Sickness Surveys *

HUNTINGTON WILLIAMS, M.D., F.A.P.H.A.

Commissioner of Health of Baltimore City

For confidence in statistics, like sausages, you must have knowledge of three things: Who made them, From what materials were they made, and For what purposes were they made.

From *Sir Arthur Newsholme*, 1921

THIS member of the panel, as a medical health officer, has been asked to discuss whether or not it may be desirable to make morbidity surveys a regular function of the health department; and further, whether the diagnostic material thus collected from lay informants would be reliable and valuable.

It is true that during the past fifteen years and more a good deal of this sort of information has been gathered in the Eastern Health District of Baltimore, especially with the aid of Dr. W. Thurber Fales, the City Health Department's Director of Statistics, and Dr. Lowell J. Reed and other coworkers in the Johns Hopkins School of Hygiene and Public Health. These cumulative family studies, based on repeated household inquiries, provide an unmatched backlog of information against which special health investigations may be placed for study. This has been done in syphilis, in tuberculosis, and for other health conditions. The Eastern Health District material was used by Jean Downes and Selwyn D. Collins as in their paper "A Study of Illness among Families in the Eastern Health District of Baltimore," in the *Milbank Memorial Fund Quarterly* of January, 1940. Such use of sickness survey material was of value to the Baltimore City Committee on Medical Care in laying the groundwork for the newly established Baltimore City Medical Care Program within the City Health Department. I am led to believe, however, that small scale local sample surveys compounded into a general national series of figures would be of little value on a local basis and that such small scale sampling surveys would probably not be desirable as a routine function of a local health department.

National figures, such as the monthly sickness surveys published by the British Ministry of Health, may have some meaning for the statistically minded, but for local interpretation they may be misleading in the way that a national weather forecast might be valueless when used on a local basis.

There is no doubt that the local health officer would welcome more exact information on the amount of illness, beyond the reported communicable disease cases, that occurs within his jurisdiction. He would like to know the types and causes and duration of such disabilities. He will do his best to cooperate with those who desire to make such investigations. However, he will be dubious about the reliability of "medical facts" and "diagnoses" provided by lay informers. For instance, when do common colds become an out-

* Excerpts from remarks presented at a Joint Session of the Biometrics Section of the American Statistical Association, Biometrics Society, and the Statistics Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

break of grippe, and when does a series of outbreaks of grippe become an epidemic of influenza, in the absence of a lively series of press releases resulting from some colds among the staff of the local newspaper, perhaps in November or February, when the temperature is changeable and it is wet underfoot? Or, when is poliomyelitis not poliomyelitis in the absence of paralysis or detectable muscle weakness?

Sir Arthur Newsholme and Dr. Otto Eichel, who was Dr. Hermann M. Biggs's statistical director in Albany, have taught us to be careful in our use of statistics, and Frost used to tell us in the 1930's that diphtheria might just be on a long-range decline, and that all the credit perhaps should not be given to the toxoid we were pumping into the children. On the other hand, Godfrey's studies of the statistics of measles have made it clear that the health officer must aim at preventing measles *deaths* under 3 years of age and not at preventing measles *cases* in school age, as earlier health officers vainly and mistakenly tried to do.

Let me close with some comments recently made by Dr. Charlotte Silverman on the need for care in interpreting the significance of the crude results of mass x-ray surveys of various local groups for tuberculosis control:

"There are many confusing variables. They relate to the manner in which the groups are selected for mass radiography and the extent of participation of the group members; to the radiographic equipment employed; the extent to which reading of small films is supplemented by large films; to the skill and experience of the film reader; to the extent to which x-ray interpretation is supplemented by follow-up clinical and laboratory investigations; and, finally, to the criteria used in defining and classifying 'cases' of tuberculosis upon which rates and estimates are based. While mass radiography of the chest undoubtedly has its place in the epidemiologic attack upon tuberculosis, the values and limitations of this procedure have not yet been clearly delineated."

In spite of what has been said, this member of the panel wishes to state that he is enthusiastic for whatever will result in better planning and execution of morbidity surveys. However, he feels there is a real need for a clearer understanding of the many pitfalls that stand in the way of success in this difficult field of endeavor. Also, further consideration is needed in order that future surveys may be planned so as to be more useful to the local health official if he is expected to be an active collaborator in such survey efforts.

How Processing Affects Nutritive Values of Grain Foods*

FREDERIC W. NORDSIEK, F.A.P.H.A.
Standard Brands Incorporated, New York, N. Y.

SET a starving man down in a vegetable garden and he could quickly stay his hunger; but set him down in a field of wheat—and he would remain hungry. This paradox arises from the fact that wheat, like all the grain crops, usually requires fairly extensive processing before it is acceptable as food for the human being. The results of such processing, and their correction through enrichment and related means, are a significant element in the nutritional welfare. For the grain foods today remain, despite a gradual decline in their consumption during the 20th century, the largest single major food group in this country. In the United States, 6 grains are consumed by human beings in sizable amounts. They are, approximately in the order of their preponderance, wheat, corn, rice, oats, rye, and barley. Wheat is by a large margin the major American cereal and wheat and corn together constitute some 90 per cent of total human grain consumption.[1]

Preparation of the grains for food use may be segregated into 4 basic procedures: (1) milling, (2) manufacture, (3) restoration of nutrients to original levels, and (4) supplementation with nutrients to augmented levels.

MILLING

The first of the 4 basic procedures, *milling*, is applied to practically all of the grains consumed in this country. For example, census reports on the flour industry reveal that less than 2 per cent of the wheat flour manufactured is the whole grain product, the remainder being milled white flour.[2] Milling, as is well known, comprises removal of the outer chaffy husk or hull from the grain kernel, followed by separation of the bran coats and the germ or embryo. The endosperm remains; this may be left whole as in the instance of rice, may be broken into coarse particles like corn grits, or may be ground fine to make meals and flours.

Various "undermilling" processes exist that are designed to retain part of the bran and germ in the portion of the grain used for food. In addition, methods are available for transfer of nutrients from the outer layers of the grain kernel to the endosperm, prior to milling.[3-5] At present such procedures have limited use.

MANUFACTURE

After milling, some cereal foods, like rice, are prepared for consumption by merely boiling. Preparation of other grain foods, namely bread and related baked products, macaroni and noodle products, and ready-to-eat breakfast cereals, involves the second phase of processing, which we have designated as *manufacture*. Manufacture frequently enhances nutritive value because of nutritious ingredients, such as milk or eggs, customarily added to certain products at this time. The only nutrient loss of moment during manufacture is a reduction in thiamine resulting from the heat

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

of baking bread and similar foods, and from other heat treatment, such as toasting, applied in the making of prepared breakfast cereals.[6] This reduction is readily corrected. For example, in the making of enriched bread a surplus of thiamine of approximately 20 per cent is added to the dough, to offset heat losses during baking. In the making of prepared breakfast cereals, a fortifying mixture is frequently sprayed upon the product after toasting, while the product is still hot enough to dissipate the moisture of the spray, but not hot enough to affect thiamine. Grain food processors have little concern with the protection from destruction by light of factors like riboflavin. Furthermore, oxidation-labile factors like ascorbic acid do not occur in significant amounts in the grains, so that these industries have no problem with prevention of oxidative nutrient losses. It is of interest to note that a fortuitous increase in iron content frequently occurs, during both milling and manufacture, as a result of the use of iron and steel equipment.

RESTORATION OF NUTRIENTS

We have seen that consumers in general demand grain foods in the milled form, and also that major grain foods in addition undergo the processing involved in manufacture. Since milling removes the nutrient-rich bran and germ, it produces a significant change in nutritive value; and manufacture, as has been shown, may cause an additional loss of thiamine. The practical solution to the problem of these losses has proved to be *restoration of nutrients,* which has been designated as the third of the 4 basic operations in cereal processing. Restoration is practical because synthetic vitamins, and wholesome assimilable mineral salts, are inexpensive and available in plentiful supply, and because such vitamins and minerals may be added to grain foods without altering flavor or appearance.

The nutrients selected for addition to grain foods, and the levels used, are based on various standards and recommendations. The U. S. Food and Drug Administration has promulgated definitions and standards of identity for enriched flours and farina,[7] enriched macaroni products and enriched noodle products,[8] and enriched corn grits and enriched corn meals.[9] A similar definition and standard of identity for enriched breads and rolls was proposed in 1943,[10] and has been the basis of a practical program since then. For breakfast cereals, the Food and Nutrition Board of the National Research Council has recommended nutrients and levels for fortification.[3] No standards or recommendations are available for fortification of rice, but such fortification is now practised to a limited extent on a voluntary basis, using the nutrients and levels of the official enriched flour standard, with riboflavin omitted because its yellow color would be foreign to the product.[11]

Flours and meals are enriched by use of a powdered vitamin-mineral premix having the same fine particle size as the product. This premix is blended with the flour at the mill by means of continuous automatic machinery, in a proportion of ½ to 1 ounce per 100 lb. of flour. Enrichment of grain foods of large particle size, such as corn grits or rice, at first presented serious difficulty. A powdered premix added to such products would not remain uniformly distributed, and furthermore would be leached out by the water used for the washing and cooking these foods undergo before consumption. The clever expedient developed to overcome these difficulties is the use of actual corn grits or rice kernels that are impregnated with the enrichment nutrients in a high concentration, and then coated with an edible, water-resistant film. This film helps protect the nutrients against losses in washing and cooking. The "super-enriched"

particles do not differ significantly in appearance from the rest of the product. The concentrations of added nutrients in the super-enriched particles are so designed that for corn grits they are mixed into the product in a ratio of 1 lb. to 800 lb., for rice in a ratio of 1 lb. to 200 lb. These proportions assure that servings of the foods as normally eaten contain the proper concentration of enrichment nutrients.

Enriched bread may be made by using enriched flour, but commercially produced bread is frequently enriched by means of enrichment wafers. Considerable research was necessary to design such enrichment supplements, in order to provide the desired nutrient levels, but still avoid exceeding the maximum limits that are imposed by the standards. The possibility of exceeding maximum limits arises from the fact that the regular bread ingredients are significant sources of the enrichment nutrients. Thus the yeast used to leaven bread provides roughly 3 per cent of the thiamine, 13 per cent of the riboflavin, and 4 per cent of the niacin in enriched bread. White flour contributes 15 per cent of the thiamine, 9 per cent of the riboflavin, 25 per cent of the niacin, and over 40 per cent of the iron. When dry nonfat milk solids are included in the bread formula in the frequently used proportion of 3 lb. to 100 lb. of flour, they supply 19 per cent of the riboflavin in enriched bread.

Macaroni and noodle products made in continuous presses are enriched by a procedure similar to the one described for flour; when made by means of batch operations they are enriched by use of wafers similar to bread enrichment tablets. A fortified dry yeast preparation is also supplied to this industry for enriching purposes.

SUPPLEMENTATION WITH NUTRIENTS

Enrichment levels for riboflavin, as we shall see in a moment, transcend the restoration principle in that they go considerably higher than the levels found in natural whole grains. Therefore, the discussion just concluded of *restoration of nutrients* has impinged upon our fourth and final fundamental operation in the processing of grain foods, *supplementation with nutrients*. Calcium is included as an optional ingredient in the enrichment standards, also at levels ranging considerably higher than those found in the original grain. Vitamin D is the second optional enrichment ingredient, and since this vitamin does not occur in the grains in significant amounts, its use is tantamount to supplementation rather than restoration.

The nonfat dry milk solids frequently used in commercial breads have been shown to contribute riboflavin; this ingredient also enhances protein value and adds calcium. Other nutritive supplements permitted by federal standards of identity for grain foods include various milk products, eggs, wheat germ, soya products, and inactive dry yeast. Recently published reports show the nutritive advantages gained by such supplementation.[12-14]

CUMULATIVE EFFECTS

Having reviewed the fundamentals of the effects of the various phases of cereal food processing upon nutritive values, let us consider these effects in quantitative terms, choosing for illustration the leading grain food, bread. Table 1 shows values for thiamine, riboflavin, niacin, and iron in whole

TABLE 1

Nutrient Values of Various Breads
Milligrams per Pound

	Whole Wheat Bread	*Unenriched White Bread*	*Enriched White Bread*
Thiamine	1.3	0.3	1.5
Riboflavin	0.7	0.3	1.2
Niacin	15.9	3.6	12.5
Iron	11.3	3.6	10.3
Calcium	276	236*	550

* 300 mg. per lb. when made with 3 lb. nonfat milk solids per 100 lb. flour.

wheat bread, unenriched white bread and enriched white bread. Calcium is shown for whole wheat and unenriched white breads, for bread enriched to the level provided as optional in the proposed standard, and for bread not enriched with calcium but containing the frequently used 3 lb. of nonfat dry milk solids per 100 lb. of flour.[15] Values for whole wheat and white breads are variable; those shown were chosen arbitrarily from one of the standard reference manuals.[16] Values for enriched products also may vary within the limits imposed by the standards; shown here are median values.

All 5 nutrients are, of course, lower in the white bread than in the whole wheat bread, as a result of the milling of the flour. Enrichment, however, accomplishes restoration to approximately whole grain levels for thiamine, niacin, and iron. For riboflavin, in contrast, enrichment produces a level considerably higher than that in the original grain. This high level results from the rationale followed in establishment of the enrichment standards, which leaned as much toward correction of recognized dietary deficiencies as toward restoration of whole grain levels. This policy has been set forth at length by the Food and Drug Administration.[17]

Calcium, like riboflavin, rises well above whole grain levels if enriched to median values. When not added by enrichment, but provided by a commonly used percentage of milk solids, calcium returns to approximately whole grain levels. Baked foods made with enriched self-rising flour also supply high levels of calcium, as this nutrient is required rather than optional in enriched self-rising flour, and the maximum calcium level set by this standard is over twice as high as the maximum set for regular enriched flour.[7]

PRESENT EXTENT OF ENRICHMENT

During the late World War emergency, enrichment of all bakers' white breads and rolls was required by War Food Order No. 1 of the War Food Administration. This order is of course no longer in effect during current non-emergency times. The only laws at present requiring enrichment are those enacted by various states. At this writing approximately half of the states have in effect laws requiring enrichment, and presumably others will consider such legislation. All of the state enrichment laws include wheaten foods, and a number of the southern states, where much corn is consumed, extend the enrichment requirement to corn products. Enrichment was widespread on a voluntary basis before any mandatory enrichment laws existed, and at present, data on the sale of enrichment preparations in states not having such laws indicate that voluntary enrichment is still carried out on a large scale.

SUMMARY

In general, consumers demand grain foods in milled and manufactured form. These processing operations reduce certain nutrients present in the original grains. Since cereals are a major American food, this nutrient loss originally constituted a serious nutritional problem. The practical answer to this problem has proved to be enrichment, restoration, or fortification, mainly by the use of synthetic vitamins and assimilable mineral salts. The rationale followed in establishing enrichment levels has led on occasion to concentrations of nutrients higher than those in the natural whole grain. This fact, plus the customary use of supplementary nutritive ingredients in the making of certain grain foods, means that in some respects the milled and manufactured products may be more nutritious than the grains from which they are made.

Courses in the Diagnosis and Treatment of Poliomyelitis

The National Foundation for Infantile Paralysis, Inc. announces short courses in the diagnosis and treatment of poliomyelitis patients for physicians as follows:

Training Center	*Scheduled Courses*	*For Detailed Information and for enrollment write to:*
Children's Hospital Boston, Mass.	June 13–17 Aug. 15–19	William T. Green, M.D.
City Hospital Cleveland, Ohio	July 18–23 Aug. 8–13 Aug. 29–Sept. 3	John A. Toomey, M.D. Dept. of Contagious Diseases
D. T. Watson School of Physical Therapy Leetsdale, Pa.	1–3 weeks, depending on need of each individual. Dates to be specially arranged.	Jessie Wright, M.D. Medical Director
Georgia Warm Springs Foundation Warm Springs, Ga.	3–6 months, starting July 5, and October 3.	Robert L. Bennett, M.D. Director of Physical Medicine
Stanford University School of Medicine San Francisco, Calif.	3 days—probably the second week in July	W. H. Northway, M.D. Assistant Dean
University of Colorado Medical Center Denver, Colo.	May 23–28 Nov. 14–19	Winona C. Campbell, M.D. Director of Poliomyelitis Teaching Program

Nutrient Retention During Canned Food Production*

E. J. CAMERON, PH.D., R. W. PILCHER, PH.D., AND L. E. CLIFCORN, PH.D.

National Canners Association, Washington, D. C.; American Can Company, Maywood, Ill.; and Continental Can Company, Chicago, Ill.

IT is well established that the nutritive values of foods at the time of consumption may be conditioned by operations involved in home preparation or in commercial food processing. Kitchen procedures such as boiling, baking, broiling, or roasting employed to render raw foods edible or acceptable reduce the amounts of certain nutrients initially present in the raw materials.[1-5] Likewise, operations in commercial milling, dehydration, freezing, canning, or other food preserving industries may also affect the nutrient composition of raw foods. The mechanisms causing these changes have been described elsewhere.[6]

In the current National Canners Association-Can Manufacturers Institute Nutrition Program[7-9] controlled studies under commercial conditions were made to develop more complete information on the effect of canning operations on nutrient retention in raw foods. These investigations were designed to avoid the criticisms[6] which can be applied to similar investigations in the past in which results on small scale laboratory packs have been extrapolated to commercial practices. Two general types of retention studies were made; the so-called "overall" vitamin retentions of the complete canning procedure, and specific retentions during particular operations within canning procedures.

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

ESTIMATION OF VITAMIN RETENTION

In work on vitamin retention during canning, several methods for expressing the results obtained may be used. The most common method is to compare the vitamin content of the raw material and the finished canned product per unit weight, calculated on the dry basis. This method is not free from criticism but it is the most convenient yet suggested. From the standpoint of practical nutrition the errors involved are of questionable significance. Likewise, expression of vitamin retention in terms of percentages, rather than by comparison of the initial and final vitamin content simplifies handling of the data. Consequently, these two conventions have been followed in the following discussions.

OVERALL VITAMIN RETENTIONS

The so-called "overall" vitamin retention reflects the degree of vitamin conservation attained during the sequence of operations required to convert the raw material into the finished canned product. In this presentation, only vitamin retention data were considered which had been obtained during actual commercial canning operations in studies sponsored by the NCA-CMI program[10-12] or in related work undertaken in the authors' laboratories, both published[13,14] and unpublished.

Tables 1 through 3 present the overall ascorbic acid, carotene, niacin, ribo-

flavin, and thiamine retentions observed in a number of products during actual commercial canning operations. The products chosen for this illustration are subjected during canning to diverse operations which influence vitamin retention such as peeling, cutting, extraction, comminution, and so forth.[15] The overall vitamin retentions observed in the commercial canning of these representative foods should therefore reflect the general situation with respect to conservation of essential nutrients in canned foods as a class. For the purposes of this exposition, no distinction was made in certain instances for style of pack or variety. The data shown for asparagus may include both white and green asparagus packed as whole spears or cuts; Alaska and sweet peas have been considered together, and the available data observed for all varieties of green beans packed as whole beans or cut beans have been grouped. As indicated in the tables, the amount of available data varied from 4 observations made on the overall retention of carotene in yellow corn to 93 on the retention of ascorbic acid in grapefruit juice. Where 30 or more observations were available, frequency distributions were calculated and the maximum and minimum retentions shown represent the figures within which 90 per cent of the observations were found to fall. By this procedure, observations which were unusually high or favorable, or which were so low as to indicate atypical conditions, were eliminated from consideration.

With respect to overall ascorbic acid retention, the data (Table 1) indicate that the canning procedures used for asparagus and the citrus juices effect very high retentions of this nutrient; for the latter products, the minimum to maximum variations or ranges of retention are small and the mean retentions are more than 90 per cent. The range of retention of this vitamin in tomato juice is more variable and this is also true of the products subjected to relatively severe blanching procedures, namely, green beans, Lima beans and peas. In all the products shown, however, the mean percentages of ascorbic acid retention may still be considered substantial, especially if translated into the percentages of the daily adult requirement for ascorbic acid supplied by a usual or convenient serving of the foods. The data on carotene retentions, also shown in Table 1, substantiate the known fact that commercial canning procedures have only slight effects on this factor. The mean carotene retentions for the products listed range from 67 to 97 per cent.

The data on niacin retentions (Table 2) suggest that, for most of the

products listed, the canning procedures involved have small effect on this nutrient. The lowest mean niacin retention was 65 per cent in the case of peas. For the remaining products, mean niacin retentions of 85 to 98 per cent were observed. Riboflavin retentions (Table 2) during canning are to be considered excellent from the standpoint of the ranges of retention and the indicated mean retentions which ranged from 82 to 100 per cent.

Great variability in overall retention is to be noted in the case of thiamine (Table 3). This factor is heat-labile and is also known to be extracted from foods during blanching operations. Acid products such as peaches, tomatoes, and tomato juice, which do not require blanching during preparation and which are customarily processed at 212° F., show high mean retentions of thiamine (76 to 96 per cent). The low-acid products (asparagus, corn, green beans, Lima beans, and peas) subjected to blanching, to relatively severe heat processes, or to both, show more variable ranges of retention and, in general, lower mean retentions (34 to 71 per cent). None of the products considered, however, can be regarded as an outstanding source of this nutrient even in the raw state, when compared with certain foods of animal origin.

RETENTIONS DURING BLANCHING

In addition to studies on overall nutrient retentions, surveys have been made of specific canning operations to determine which steps during the preparation and processing of canned food products are of most serious concern. Such step by step studies have revealed that blanching required in the canning of certain products is one of the operations where sacrifice of vitamin content may occur. Consequently, considerable effort has been devoted to investigation of this operation.

Experience has indicated that the blanching of raw vegetables in hot or boiling water or in live steam has distinct advantages. Blanching is used to obtain the desired appearance and

flavor in the final product, to effect proper fill of container and to reduce internal can pressure during heat sterilization by the elimination of air and other gases from the product and the container. There are other functions of the blanch, such as destruction of enzymes, but these are not commonly regarded as the primary objectives of the operation.

Any review of blanching schedules followed throughout the industry for the same product will show that the practices employed vary widely with respect to the time and temperature of blanching. Some canners have fixed blanching schedules to meet certain operational requirements. For the most part, however, blanching schedules have been set so as to attain desired or mandatory quality levels in the final product.

In most commercial canning operations, hot water blanching is employed in the preparation of certain vegetables for canning. This operation establishes conditions favorable to an extraction process whereby water-soluble nutrients, including the vitamins ascorbic acid, thiamine, riboflavin, and niacin, may be dissolved. The extent of such leaching depends upon the nature and maturity of the product, the amount of raw flesh of the vegetable exposed through cutting and bruising, and the time and temperature of the blanch. Where steam blanching is used, extraction of the water-soluble nutrients is not as great as may occur in hot water blanchers.

Information obtained in the NCA-CMI program surveys of specific operations of vegetable canning procedures,[10-12] together with information obtained in the laboratories of the authors, published [13] and unpublished, has been summarized and condensed to show the retentions of the above nutrients in blanched vegetables. The results of all of the commercial blanches studied are presented in Tables 4 and 5. The same conventions with respect to handling the data used in the case of overall retentions have been followed.

Ascorbic acid retentions during blanching (Table 4) reveal the best retentions for asparagus (mean—95 per cent), while the lowest and most variable retentions are to be observed for spinach (mean—67 per cent). To ex-

Lima Beans	8	100	59	76	12	77	36	58
Peas	37	87	67	75	60	100	73	88
Spinach	37	100	78	88	85	100	67	85

plain these variations, one has to know only that the comparatively small surface area of the asparagus, combined with the relatively short blanching time for the product, would tend to minimize destructive effects. In contrast, spinach is a product with a thin, extensive surface area due to its leaf-like character. Also, considerably more severe blanching conditions were imposed upon this product than was the case with asparagus, thus producing more favorable conditions for solution of water-soluble material. The retention of niacin during blanching (Table 4) suggests that niacin is more firmly bound in the products studied than ascorbic acid, since the retention generally seems to be of a higher order. It also appears that this vitamin is not as water-soluble as other members of the vitamin B-complex. Mean retentions of this nutrient for most of the products were in excess of 80 per cent. Riboflavin retentions during blanching (Table 5) are rather good in most vegetables with the exception of Lima beans where the range is rather wide. Lima beans and peas showed mean retentions of about 75 per cent; riboflavin retentions in the other products listed were in excess of 80 per cent.

The retention of thiamine during blanching is also portrayed in Table 5. One interesting item in this table is the low mean retention of thiamine in Lima beans, namely, 58 per cent, with a range of retention for this specific operation of 36 to 77 per cent. While niacin and riboflavin retentions for all five vegetables listed were generally of the same order, the retention of thiamine in Lima beans dropped to a mean of 58 per cent as compared to mean retentions of 76 and 81 per cent for riboflavin and niacin, respectively. While the data presented may be influenced by the number of observations involved, this finding might deserve further investigation.

RETENTIONS DURING THERMAL PROCESSING

The heat-labile properties of thiamine raise the question as to retention of this vitamin during heat sterilization of canned foods. Other nutrients seem little affected by this operation. The effect of the pH of the product being processed is of importance, although there is a difference of opinion as to the specific importance of this variable upon thiamine retention during heat sterilization. It has been postulated that there are materials in some products which stabilize thiamine toward heat and that these materials may be of considerable importance in effecting maximum retention of this particular nutrient. In general, products such as tomatoes and tomato juice which are sterilized at relatively low temperatures because of their low pH, have a high degree of retention of thiamine while low retentions are found in products such as whole kernel corn. These low retentions may be explained by the relatively severe heat process necessary for sterilization. Typical thiamine retentions in vegetables during commercial thermal processing are the data reported by Clifcorn and Heberlein[13] shown in Table 6. The effect of thermal processing upon the thiamine content of canned foods is conditioned to a large extent by the time and temperature relationship of the sterilization operation. This relationship is, in turn, affected by different can sizes and the nature of the product, with particular reference to whether heat transfer occurs by convection or by conductance during the thermal processing operation.

IMPROVED VITAMIN RETENTIONS

Since blanching is a major factor conditioning vitamin retention in certain canning operations, it has been the point of emphasis as far as present and future studies are concerned. Experiments are now under way on new types of experi-

mental blanchers embodying principles which might be more generally applied in commercial blanching in the future. With respect to existing equipment, studies on the effect of the time and temperature relationships in hot water blanching have revealed that the high-temperature short-time blanches are generally superior from the standpoint of maximum vitamin retention. In all instances this type of blanch yielded the same quality of product as obtained by low-temperature long-time blanches. With the green beans, the short-time high-temperature blanch was definitely superior from the quality standpoint. More detailed attention to the time and temperature relationships in hot water blanching, more extensive use of steam blanching, and possibly equipment improvement should reduce significantly the sacrifices of water-soluble nutrients during this particular step in the preparation of the products for canning.

New principles such as non-aqueous or steam pressure blanching also have been studied which would require radical changes in existing equipment. Preliminary work by Ives[16] has shown that very favorable ascorbic acid retentions result from application of these two new principles but their effect on final product quality may be questionable, or at best is still to be established. Consequently, the indicated approach to improved nutrient retention during blanching by modified use of existing equipment is to be considered the most practical at this time.

With respect to improved retention of heat-labile factors such as thiamine, the tendency of the canning industry is to

employ more high-temperature short-time processes. The value of such processes in thiamine retention have been shown by Greenwood, *et al.*[17] This work has also shown the effect of increased can size on vitamin retention in the same conduction heating product; namely, as can size increased, the degree of vitamin retention decreased due to the relatively more severe heat processes necessary for the larger sizes of container. Likewise, these investigators studied the relationship existing between vitamin retention at the periphery of the container and retention of the same vitamin in the center. It was found that a gradient of vitamin retention exists in conduction heating products, with higher retentions being observed at the center of the container. This is due to the fact that during long heat processes the product adjacent to the walls of the container receives a more severe heat treatment than that at the center of the can.

Greenwood, *et al.* also related the sterilizing value of the process (F_0) with respect to thiamine retention. It was found that with each 18° F. rise in temperature, the rate of thiamine destruction is approximately doubled while the rate of bacterial destruction is increased approximately tenfold. These data suggest that increased thiamine retention will result from application of high-temperature short-time thermal processing schedules wherever possible. The work of Greenwood, *et al.* has been confirmed by later studies, in which thiamine retentions in cream style corn and vegetable puree sterilized by high-short and conventional processing methods have been compared.[14]

New methods for agitation of foods during processing also have shown improved thiamine retention over conventional processing techniques.[18] Agitation during processing increases the rate of heat penetration into the container so that application of the necessary effective heat is attained in shorter time with increased retention of thiamine. Extended use of the high-short and agitating types of process should result in even greater retentions of heat-labile nutrients than is now accomplished commercially.

SUMMARY

Operations commonly involved in the home preparation or in the commercial processing or preservation of food may affect the initial nutrient compositions. Such operations are necessary to render food edible or attractive, attain required or desired levels of food quality, or insure the success of commercial food processing or preserving procedures.

A considerable volume of literature has been developed on nutrient retention during commercial canning, and the data obtained in major studies in this field are summarized and discussed. Vitamin retentions vary with the product and nutrient under consideration. However, raw products significantly high in specific nutrients remain significant sources after canning. Certain operations, notably blanching, are subject to improvement, and studies of this type currently in progress are described. The newer types of high-short thermal processing show considerable promise of improved retention of heat-labile vitamins in products to which such processes may be applied.

ACKNOWLEDGMENT—The authors gratefully acknowledge the considerable assistance received from Mr. D. G. Heberlein, Drs. Margaret Ives and J. F. Feaster, and Miss Edwyna Preiss in preparation of the manuscript.

Massachusetts Public Health Conference

The three day Massachusetts Public Health Conference promises a varied menu of well balanced professional nourishment. It will be held at the University of Massachusetts at Amherst, June 15, 16, and 17.

The opening session on Wednesday morning will be concerned with new horizons for public health personnel. In the evening, the Honorable Oscar R. Ewing and Dr. Morris Fishbein will discuss the National Health Program.

Thursday will be given over to a wide variety of subjects and will end with the annual banquet at which will be heard a widely known speaker—his name is a dark secret.

Friday morning promises to be the high spot of the conference. Experts in mental health, heart disease, diabetes, and other special programs will outline modern concepts and relate them to the general administrative program. Dr. C.-E. A. Winslow, as the luncheon speaker, will bring the session to an inspiring close.

The Possible Significance of Milk and Water in the Spread of Virus Infections*†

GORDON C. BROWN, Sc.D.

Associate Professor of Epidemiology, Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, Mich.

SINCE milk and water have been incriminated in the spread of many bacterial diseases, such as dysentery, typhoid fever, undulant fever, tuberculosis, diphtheria, scarlet fever, septic sore throat, and tularemia, to name a few, one might assume that certain of the virus infections of man might be disseminated through these same channels. If one classifies virus diseases roughly into two groups, those whose routes of transmission are definitely known and those whose transmission is either unknown or suspected but not proved, we find that milk or water is involved in the dissemination of only one and possibly two of the agents whose mode of spread is known. This leaves a relatively small number of the second group of diseases.

Three of these diseases, herpes simplex, encephalomyocarditis, and infectious mononucleosis, to the best of my knowledge, have not been studied from the point of view of milk and water; probably because the latter has not been definitely shown to be due to a virus and because some form of contact seems most likely for the others.

Another infection of probable virus etiology, pretibial fever, recently described by Bowdoin[1] and by Daniels and Grennan,[2] has the interesting epidemiological characteristic that most of the cases in the two reported outbreaks had been swimming in or living near common water sources. No insect vector could be incriminated and further studies have not revealed the mode of spread, although Tatlock[3] was successful in passing the agent by inoculating fresh whole blood of infected individuals into young guinea pigs, hamsters, and embryonated eggs.

Thus, we are left with a consideration of 6 diseases, namely, inclusion blenorrhea or inclusion conjunctivitis, infectious hepatitis, foot-and-mouth disease, epidemic diarrhea of the new-born, Q fever, and poliomyelitis. These virus diseases of human beings are the only recognized ones with which milk or water or both have any possible relationship.

The first of these, inclusion conjunctivitis, is usually seen clinically as a disease of infants. The reservoir of the virus is a mild genitourinary disease of adults which is probably transmitted venereally and in which low grade nongonococcic urethritis is the lesion in the male and subclinical cervicitis in the female. The most common means of transfer to the eye is birth canal infection of infants during delivery. However, definite examples of inclusion conjunctivitis have apparently been contracted

* Presented before a Joint Session of the Food and Nutrition and Laboratory Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

† Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

from swimming pools, the incubation period in each case being exactly 7 days. Genitourinary discharges into the water are the probable sources of contamination. There seems to be little doubt that chlorination and other methods of disinfecting pools have cut down the incidence but are not entirely prophylactic. Experimental studies have shown that the virus can survive in untreated water for as long as 6 hours.[4] It is thought that even in the presence of chlorine, water would be dangerous if freshly contaminated by discharges from an infected individual.

Infectious hepatitis is a disease which has commanded more and more attention during recent years and which was a significant factor among our troops during the recent war. Neefe and Stokes[5] have described an outbreak of this disease in a summer camp which was apparently water-borne. Three hundred and fifty of 572 individuals in the camp became infected within a period of 7 weeks, 255 of these resulting in overt jaundice. This epidemic was characterized by an unusually high incidence, the simultaneous infection of a number of persons at the camp not in personal contact with each other, and by the apparent ease with which the agent was acquired at camp in contrast to the few cases among those in contact with infected persons developing the disease away from camp after returning home. Epidemiological evidence clearly ruled out air, fomites, biting insects, food, milk, lake water, and personal contact in the transmission of the agent during this outbreak. Well water which was exposed to the discharges of the original case through cess pools seemed to be the reservoir of infection. By means of human volunteers the agent, which passed Seitz filters, was found to be present in the blood and feces of cases but not in nasopharyngeal washings, urine, or flies. Serum produced the disease in volunteers only when administered orally, not parenterally. Water from the well which was used by all the cases produced a mild illness associated with hepatic dysfunction, in 4 of 5 volunteers who subsequently were immune to the feces agent from other cases. Since bacteriological studies showed evidence of fecal contamination in this water and transmission experiments proved it contained an agent, this appears to be the first evidence of natural transmission to man of any virus agent by water.

Our laboratory observed an outbreak in a rural school group which resulted in jaundice of 41 of 74 pupils during a period of four months.[6] The source of infection was apparently water.

Gauld[7] in describing field studies of infectious hepatitis among troops in the Mediterranean Theater of operations was impressed with the fact that it seemed to be a disease of fall and winter, and he thought the epidemiological pattern was strongly suggestive of respiratory spread rather than by gastrointestinal or insect routes. However, he described one explosive outbreak in a mountain infantry regiment which was believed to have resulted from drinking contaminated well water.

Neefe, Stokes, Baty, and Reinhold,[8] using human volunteers who received feces infected water treated in various ways, found that the causative agent of infectious hepatitis was not inactivated or attenuated by a 40 minute period of contact with sufficient chlorine to provide a residual chlorine concentration of 1 p.p.m. after 30 min. of contact. Superchlorination (treating with sufficient chlorine to reach the "break-point" and provide a chlorine residual of 15 p.p.m. after 30 minutes' contact) resulted in a definite attenuation of the hepatitis agent. The agent was not completely removed or inactivated by treatment with sodium carbonate, aluminum sulfate or activated carbon. However the incidence of disease was lower, the in-

cubation periods longer, and the disease much less severe than in the control group suggesting a decrease in concentration of virus or a decrease in virulence, or both.

Further studies on disinfection of hepatitis contaminated water were reported by the Army Epidemiological Board.[9] Of 6 volunteers receiving untreated water, 5 developed hepatitis with the usual "short" incubation. Of 7 volunteers receiving the same water after filtration and coagulation, 3 developed the disease after a longer incubation period. None of 7 subjects given the same water after filtration, coagulation, and chlorination developed hepatitis. Thus, a 30 min. chlorine residual of 1 p.p.m. is probably sufficient to inactivate this agent *providing the water is properly treated prior to chlorination.*

That this disease may also be transmitted through contaminated milk supplies has been shown by Murphy, Petrie and Work[10] who incriminated this medium as the source of infection in a small outbreak of 10 cases in Georgia. All 10 cases drank raw milk from the same source and within the limits of the incubation period all developed frank jaundice. None of the non-consumers developed hepatitis although they were 20 times more numerous. Prior to the outbreak, 2 cases of the disease had occurred in a household adjoining that of the dairyman, and the 2 families had been in close, even intimate contact. The milk was handled in the open, 100 feet from a dilapidated surface toilet serving both families. Many flies were present. No evidence incriminating any other common source of infection for the 10 cases, either food or water, could be obtained. Although there was contact among some of these, the evidence did not support that means of dissemination. No virus studies were made.

Foot-and-mouth disease is a highly contagious infection of cattle, pigs, sheep, and goats, which, fortunately, is not a major problem in this country at the present time. While it is rarely transmitted to human beings, such transmission is effected by ingestion of virus contaminated food, handling the active agent (as in the laboratory), and by contact with infected animals. Since the virus is found in the blood, saliva, urine, feces, vesicular lesions, and milk of infected animals, such materials, as well as meat and dairy products, play an important rôle in the spread of infection. Boiling or pasteurizing of farm products should be adequate for control of this disease in the human population.

Epidemic diarrhea of the new-born is an acute, communicable disease of neonatal infants. The evidence that it is caused by a virus is fairly well established. Several laboratories[11-13] have isolated from stools of sick infants a filterable agent which is serially transmissible through young calves, and there is some evidence that the virus may be isolated on scarified rabbit corneas.[14-15] As far as is known the agent could be disseminated by any one of several ways, all of which reflect either respiratory or gastrointestinal contamination, which includes milk as a possibility. No sure method of controlling the disease is known except for avoiding upper respiratory infection and diarrhea among nurses and mothers and observing strict nursery technique which includes sterilization by autoclaving of the formulas.

The relationship of this disease to epidemic gastroenteritis recently described by Gordon, Ingraham, and Korns[16] is unknown. These authors reproduced the illness in series in human volunteers by oral administration of a filterable agent obtained from the stools and throat washings of adult institutionalized patients. The pattern of spread of the naturally occurring disease bore no apparent relationship to a common source distribution of milk, food, or water, and direct person to person contact was thought to be the mode of transmission.

Q fever, a rickettsial disease, is included in this review for several reasons. Rickettsiae are customarily classified with viruses rather than with bacteria on the basis of size, growth requirements, and other characteristics. The organisms causing Q fever, for example, are so small in some preparations that they are no larger than the elementary bodies of vaccinia and pass through Berkefeld N filters with ease. Furthermore, this rickettsial disease is in contrast with the spotted fever and the typhus fever groups, in that the transmission is not sharply defined as requiring an insect vector.

Epidemiological studies of Q fever have rather definitely implicated the cow with human infection. Derrick, Smith, and Brown [17] studying the disease in Australia found that 31 of 34 rural patients had close contact with cattle and 112 of 118 patients in the city of Brisbane had worked in meat works. Agglutinins for the organisms were found in the sera of some of the cattle. These workers, however, implicated ticks as playing some part at least in the transmission in that country.

The apparent lack of an insect vector in the American outbreaks and their explosive and isolated nature seems to be different from the picture in Australia. Shepard and Huebner [18] reported that 21 of 130 sera from cows in the Los Angeles area contained complement-fixing antibodies for the organisms. Although proximity to dairies by reason of residence or occupation was a common factor in more than 50 per cent of the 17 cases, none of them had intimate contact with cows suggesting some source of infection other than contact. Huebner and his coworkers [19] succeeded in recovering the rickettsia from the raw milk of 4 widely separated dairies. The organisms were not recovered from blood, urine, or feces of these cattle. The fact that nearly all the milk was transported before processing and much of it was sold raw suggested that infected milk might have served as the source of infection to man. Tests, as yet incomplete, indicate that the two methods of pasteurization in general use in large commercial milk plants have different effects on the organisms. The flash method, rendered the raw milk infected with rickettsia apparently non-infectious for guinea pigs, but the vat method, or 143° C. for 30 minutes, did not entirely inactivate all the organisms (unpublished data, Huebner, 1948).

Three apparently milk-borne epidemics of poliomyelitis have been described. Dingman [20] in 1916 reported 8 cases in 3 different boarding houses all of which used raw milk from the same source. Two children at the house of the dairyman had poliomyelitis prior to the onset of disease among these 8 whose onsets were all within a 2 day period. At one boarding house only those children who used the milk became ill, and among other families who used the same milk during this period, but who boiled it, no cases appeared.

Knapp, Godfrey, and Aycock [21] described an outbreak of 8 paralytic cases within an 11 day period among drinkers of the same raw milk supply. A boy employed at the dairy was milking cows and handling milk for a period of 4 days while in the acute stage of the disease. The 8 cases were further traced to one delivery of nights' milk while no cases occurred among those receiving mornings' milk from the same dealer. There was no record of direct contact between any of the cases and indirect in only 1.

Aycock [22] described a larger epidemic in Broadstairs, England, where the distribution of cases, in point of time, indicated simultaneous infection. Of a total of 75 cases, 69 could be associated with milk from one dealer. All the 43 paralytic cases used this milk. The milk was apparently pasteurized by the flash method only, in muggy weather, and was not bottled. No illness suggestive of

poliomyelitis had occurred in any of the dairy workers or anyone associated with the milk supply.

It is perhaps significant that the evidence incriminating milk in the above mentioned epidemics is based entirely upon epidemiological and clinical evidence. No virus studies were made on either the milk supplies or specimens from the cases.

Although some evidence is available to show that pasteurization temperatures are usually sufficient to inactivate poliomyelitis virus when suspended in water, the possible protective effect of milk on the virus, requiring higher temperatures for inactivation, has received scant attention. Lawson and Melnick [23] tested rodent adapted strains of virus and spontaneous mouse encephalomyelitis virus in both milk and water at different temperatures for 30 min. Their findings showed that a milk medium enables a 10 per cent suspension of the virus to withstand from 5 to 10° C. more heat for 30 min. than when the infected tissues were suspended in water and that milk seems to exert a protective action on destruction of virus by heat as may other proteins. The concentration of virus played a rôle in this phenomenon, the more dilute the virus suspension, the less heat being required to inactivate. However, with concentrated suspensions, occasional traces of virus could be detected after 30 min. at 65 and even 70° C. which is well above the usual temperature of pasteurization. However, there were no phosphatase controls and no evidence that thorough mixing had occurred. As previously mentioned, these experiments were performed with strains of murine poliomyelitis and information is still lacking on the susceptibility to heat of human strains of virus suspended in milk. A similar experiment performed by Ridenour but employing a setup more nearly approximating proper pasteurization technique and checked by means of the phosphatase test, showed that virus was readily inactivated under these conditions.[24]

The significance of water as a vehicle in the spread of this virus has been an enigma for years. Since Kling [25] reported the recovery of virus from well water used for drinking purposes by a case of the disease, this medium has been suspected but no one has duplicated his findings, with the possible exception of the report by Toomey, Takacs, and Weaver [26] who isolated an agent from creek water. In both these instances however, fecal contamination was not only possible but quite probable. In the latter case a drainage ditch containing sewage emptied into the creek near the source of water for these studies. Since the human intestinal tract represents the greatest single source of virus it is only natural that raw sewage has been found to contain it in large quantities. The repeated isolations of virus from sewage by Paul and Trask and others [27, 28] have not been a surprise, especially since the samples were usually taken near the outlet.

Since the virus of poliomyelitis is resistant to a wide variety of chemicals the efficacy of water treatment in removing this potential source of infection has been subject to much consideration, debate, and a certain amount of experimentation. Carlson, Ridenour, and McKhann [29] added virus to city water and to raw untreated water and simulated conditions of coagulation and sedimentation, sand filtration, absorption on activated charcoal, storage, and aeration. These procedures failed to remove the virus completely from such artificially, heavily contaminated water. The observers found that ultra-violet light from an artificial source has a greater effect on destruction of the virus than that exerted by direct sunlight and is more effective in inactivating or destroying virus suspended in water than any single purification method commonly utilized. The same authors [30] found

that activated sludge in amounts as low as 1,100 p.p.m. with 6 hours aeration will remove or inactivate virus as judged by infectivity tests in mice. Heavier concentrations of sludge with longer aeration periods largely eliminate the infectivity.

The effect of chlorine on poliomyelitis virus has been investigated by several workers. Kempf and Soule[31] found that a concentration of 0.55 p.p.m. did not inactivate the virus in 1.5 hr. but was effective after a 4 hr. period of contact. The residual chlorine was found to be 0.35 p.p.m. The same workers using calcium and sodium hypochlorite found that 1.0 p.p.m. for 25 min. had no effect on the virus.[32] After 4 hr. with a residual chlorine of 0.2 p.p.m. the material was still infectious. Their conclusions were that while virus can be inactivated by chlorine the amounts needed are greater than the normal residual concentrations carried in disinfection of drinking water and swimming pools and also that the time required to inactivate virus is beyond practical limits.

The above conclusions were based on the ether orthotolidine or the starch methods of determining residual chlorine which were standard at the time. These methods do not give true evaluations of the concentration of "free" uncombined chlorine or of any other solution containing ammonia or nitrogenous compounds. In the presence of such materials, chlorine compounds are formed which, although having higher oxidation potentials, have less disinfectant capacities.

By means of the orthotolidine-arsenite test it is possible to measure more accurately the concentration of "free" uncombined chlorine in the hypochlorous state in organically polluted solutions. Ridenour and Ingols[33] using this test found that a "free" chlorine residual of 0.2 p.p.m. will inactivate a 1:500 dilution of virus after 10 min. or 0.1 p.p.m. after 30 min. These amounts of "free" chlorine are well within the range of practical doses used in water treatment and in swimming pool sanitation. The effectiveness of "free" chlorine residuals is independent of the type of chlorine-bearing compound as long as the equivalent oxidation-potential of free chlorine exists.

Lensen, Rhian, and Stebbins,[34] using partially purified virus and testing for "free" chlorine and chloramine, found that 0.5 per cent virus was inactivated in less than 10 min. when the chloramine residual was as low as 0.05 p.p.m. if the pH was near neutrality. The outcome of their experiments suggests a decrease in the virucidal activity of chlorine with increasing alkalinity of the medium.

A recent survey by Dempster[35] of 121 cities having populations in excess of 25,000 produced evidence of another nature. It was found that cities with deep wells as sources of water supply had the highest case rates over the last 18 years, while those supplied by streams and lakes which would be more subject to contamination had the lowest rates. The lack of water treatment in the case of deep well water might possibly be significant but these wells were reportedly not polluted. Cities with little or no treatment of their water supply had the highest incidence of poliomyelitis and cities treating water by filtration and chlorination or softening had the lowest case rates. This is in general agreement with the report of Casey[36] on studies made in Louisiana. He found that communities with both water and sewerage systems had 26.6 cases per 100,000; those without either water or sewerage had 39.7 cases per 100,000; while those with water but without sewerage had 83.6 cases per 100,000.

In the latter type of community the rate was inversely proportional to the volume of water used, suggesting that large amounts of fluid might

serve as a dilution factor or a factor increasing the rate of flow.

Maxcy [37] has summarized the hypothetical relationship of water supplies to poliomyelitis in an excellent and critical review of the evidence up to 1943. His conclusions were that whether or not these methods of treatment are effective in inactivating or destroying the virus of poliomyelitis the fact remains that it has never been shown that the incidence of this disease is significantly associated with the quality of water supplies, and moreover no explosive outbreak has been shown to be attributed to the simultaneous exposure to a common source of water. Nevertheless, it does not seem impossible that fecal contamination of water in a supply system or a well might be a vehicle of transmission under certain conditions.

In summary, it is necessary to emphasize that, with the possible exception of infectious hepatitis, milk and water, if involved, do not represent the major vehicle in the transmission of any of the diseases herein discussed. The explosive, self-limiting character of certain epidemics of hepatitis, plus the experimental evidence of transmission by ingestion of infected material, points strongly to a common alimentary route of infection probably involving either milk or water supplies. Inclusion conjunctivitis is usually transmitted by direct contact and only occasionally through swimming pool water. Foot-and-mouth disease also is usually acquired through contact with infected animals and rarely through ingestion of dairy products. The exact mode of transmission of epidemic diarrhea of the new-born and of Q fever are unknown. It is not unlikely that milk may play a role in the spread of both these infections.

On the basis of present-day evidence the route of transmission of poliomyelitis seems to be personal association with either the oropharyngeal or the gastrointestinal discharges of infected individuals. Even though fecal contamination when present renders milk and water potential vectors of this virus, the evidence suggests that this mode of spread accounts for only occasional infection.

Medical Society Guarantees Universal Medical Care

The Alameda County, California, Medical Society has guaranteed medical care to everyone at a price he can afford to pay. As a part of this program it has added a medical social service consultant to its staff.

The social service consultant will handle requests for medical care from both individuals and health and welfare agencies. Patients who cannot pay will be referred to the Highland-Alameda County Hospital. Those who can afford to pay part of the cost will be referred to the private physicians who have agreed to accept patients under the Medical Association's part-pay plan.

The medical social consultant is Muriel B. Hunter, formerly casework supervisor at the Highland Hospital. She will study the difficulties in securing medical care that individuals and agencies report, as a basis for improving the Association's part-pay plan.

The Dentist in the National Program of Cancer Control*

AUSTIN V. DEIBERT, M.D.

Chief, Cancer Control Branch, National Cancer Institute, U. S. Public Health Service, Bethesda, Md.

THE critical position of the dentist in cancer control is clearly revealed by two prevailing conditions. First, many people have been educated to the fact that they should visit their dentist at regular intervals, and therefore the dentist has a better opportunity than the physician to examine the apparently well population. Second, a high percentage of persons with symptoms of oral cancer consult their dentist before their physician. This is easily explained by the fact that the early symptoms are seldom marked, and the patient often assumes, because of the nature and location of the lesion, that it results from trouble with the teeth. Histories of oral cancer patients who have applied to the Memorial Hospital in New York show that 60 per cent of those with cancer of the gums consulted their dentists first. It should also be mentioned that the physician may have no occasion to examine the mouth, and unless the patient complains of oral symptoms, an early lesion may go unseen. In order to control cancer, we must search it out, rather than wait for symptoms to lead the patient to seek treatment.

The National Cancer Institute is conducting a survey that will soon give an accurate measure of the cancer problem within the dentist's domain. This is a study of the incidence of all known cancer in ten metropolitan areas, well distributed geographically and representative of various living and working conditions in the United States. A survey of the same areas ten years ago provided information for comparison; so the results are expected to show whether cancer of those areas is increasing or decreasing, whether patients are consulting physicians at an earlier stage of the disease, and whether certain control measures have been effective. During the past summer, New Orleans, Denver, Atlanta, San Francisco, Chicago, and Pittsburgh were surveyed; and the remaining four areas—Detroit, Dallas and Fort Worth, Philadelphia, and Birmingham—are to be completed by the summer of 1949.

Every physician and hospital in the areas studied has received a questionnaire asking for information on each cancer patient observed or treated during a given year. Visits are made to those who fail to respond, and in this way, a high percentage of returns has been obtained. In the 1938 survey, every hospital and all but about 2 per cent of the physicians were represented in the analysis. Comparable success has been attained in the areas recently covered. When the results are analyzed, a detailed picture of the incidence of cancer in representative cities of the United States will be available, and a more accurate description of the cancer problem within the field of the dentist will be presented than ever before.

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

Hospital records indicate that the dentist often fails to recognize cancer in the early stages. About 3 out of 5 cases are missed. Under these circumstances, a considerable amount of time is usually spent in giving some form of dental treatment, which often reassures the patient that his condition is not serious. The result in many of these cases can easily be imagined—in a disease in which delay in beginning proper treatment may mean the difference between cure and death.

The National Cancer Institute, aware that dentists trained to cancer alertness could save thousands of lives a year, has initiated a broad program for assistance in the teaching of dentists and dental students to recognize the disease in its early stages. The first federal grants for this purpose were approved in 1947. Since that time, 34 dental schools approved by the Council on Dental Education of the American Dental Association have been circularized, and all but 5 have applied. Each grant provides up to $5,000 annually for cancer teaching, upon approval of a plan submitted by the school to the National Cancer Institute.

We thought it inadvisable to specify the type of improvement the school should make. Instead, the faculty is asked to review the school's present teaching methods. If a properly integrated course in cancer is not already provided, it is suggested that within the senior year, consideration be given to a curriculum in which the pathology, physiology, and biology of cancer are correlated with a weekly clinic, and that the cancer teaching program be integrated whenever possible with that of the medical school. It is further recommended that the faculty undertake to stimulate cancer research, since research programs have been shown to improve teaching and to stimulate student interest.

You may be interested in hearing how some of the dental schools are using this $5,000 grant for cancer education. A recent example is the grant to the College of Physicians and Surgeons, School of Dentistry, at San Francisco, Calif. The purpose of this project is to collect material relative to malignant tumors of the oral cavity, lips, and maxillae, in order to augment the teaching program. Among other materials collected are histories, intra-oral models, and microscopic specimens with photomicrographs and color transparencies of the lesions. This material will be prepared and organized for demonstration.

At the University of Illinois, in Chicago, the funds will be used to expand the present teaching program in diagnosis, control, and treatment of oral cancer, to coördinate activities of the various medical and dental departments, and to initiate research.

Similar programs have been planned or established in the other dental schools that have received grants. Although the sum is modest, these institutions have been able to supplement their teaching programs in various ways, and I am confident that this will provide cancer education which will strengthen future programs of cancer control.

The National Cancer Institute does not believe that training programs should be confined to potential dentists. On the contrary, it has also been a policy to extend informational services to practising dentists in order to keep them alerted to new developments in oral cancer. Many of you are aware that Service dental consultants are now assigned to every regional office of the Public Health Service. May I urge you to call on them for assistance.

We feel that one of the primary responsibilities of a public health officer —federal, state, or local—is to help instruct the practising dentist in recognition of the disease. Many are already engaged in arranging and sponsoring cancer symposia at meetings of dental

associations. We try to help in this work by supplying materials for visual education. For example, we have prepared a series of transparencies on oral cancer, and have distributed sets to strategic points throughout the country. A more ambitious undertaking, in cooperation with the American Cancer Society, is a series of movies for general practitioners, showing how to diagnose and treat various forms of the disease. One of these films, still in the planning stage, is directed toward the early diagnosis of oral malignancy. This film is planned for release by the middle of 1949.

Now for a few specific suggestions to the dentist who would aid in cancer control: By virtue of his key position in the cancer problem, the dentist has a primary responsibility in the prevention, recognition, rehabilitation, and follow-up of cancer cases. In order to meet this responsibility, he must first develop a balanced index of cancer suspicion. In other words, an appreciation of the extent of the cancer problem that falls within his area is a requisite. An estimated 500,000 persons are under treatment for cancer at any given time in the United States. About 300,000 new cases are diagnosed each year. And with these we must consider the patients who have been treated and cured, an unknown number, and also those whose disease has not been discovered. Roughly 15 per cent of all cancers occur within the range of the dentists—that is, are visible in the region of the head and neck.

These figures do not reflect the prevalence of the so-called "precancerous" lesions, which include benign tumors, leukoplakia, chronic fissures, ulcers, and keratoses. In most cases, these do not develop into cancer, but may do so if allowed to persist. Now, in the dentist's first responsibility — prevention — attention to these lesions is of major importance. The objective in each case should be to correct the causal condition, often a prolonged mechanical irritation. It is important to remove all jagged edges of teeth or fillings; to advise heavy tobacco or snuff users of early changes in the mucous membrane; to perform necessary periodontal therapy; to correct orthodontic anomalies; and to teach correct oral hygiene. These are the main considerations in cancer prophylaxis.

The general dental practitioner, like the general medical practitioner, seldom has an acceptable knowledge of the treatment and clinical course of neoplastic processes. He should be well acquainted with certain signs and symptoms that lead to a suspicion of cancer. As a routine procedure, he should perform a complete examination of the buccal cavity of every patient. If any suspicious lesions are found, palpation with the finger will help to determine the invasive nature of the lesion, by indicating the amount of swelling or induration. The lip is the most prevalent site of oral cancer and should be given special attention.

Although examination of other tissues of the head and neck are outside the dentist's realm, definite malignant signs in those areas may be detected, such as the basal and squamous cell carcinomas of the face. In addition, many subcutaneous tumors and adenopathy are revealed by visible swelling and should be noted.

If there is any suspicion of cancer or incipient cancer, the dentist should refer the patient to a competent physician or surgeon as soon as possible. The progress of an oral cancer is sometimes rapid, and a relatively short delay may considerably reduce the chance of cure. The dentist must realize that his responsibilities do not end with the care of dental anomalies, and that every malignant tumor brought under proper treatment at a sufficiently early stage may mean the saving of a human life.

The dentist who suspects that a patient has cancer may be faced with the question of whether to attempt a diagnosis. The danger of making a diagnosis of cancer from clinical appearance alone should be emphasized. A certain and specific diagnosis, even in advanced cases, can only be made through microscopic tissue examination. Without microscopic confirmation, the use of surgery or radiation that is necessary to effect a cure is unwarranted. Neither the physician nor the dentist is justified in making more than a tentative diagnosis without a tissue examination by a specialist in histopathology. The pathologist's report has been termed the "legal" diagnosis of cancer.

Whether the dentist should consider taking a specimen for biopsy depends primarily upon two factors—an understanding between the dentist and the medical profession in the area, and the dentist's ability to rule out lesions that are unquestionably nonmalignant. The first of these considerations is a problem for the dentists and physicians to settle between themselves. There can be no question, however, that dentists in the smaller communities and rural areas, where physicians are scarce or unavailable, should assume this responsibility. Actually, it may be contended that the well trained dentist is better prepared than the physician to obtain a biopsy specimen from the mouth, because of his familiarity with that site and his special equipment.

As to the second factor, it should be pointed out that sometimes the decision whether a lesion looks enough like cancer to warrant biopsy should only be made in the light of considerable experience. We can say in general, however, that a biopsy should be performed on all suspicious bone cysts, alveolar granulomas, and ulcers or swellings of the gingiva. The dentist should see that a biopsy is done on any ulceration of the tonsils, tonsillar pillars, floor of the mouth, gingival buccal gutter, or hard palate that shows neoplastic characteristics. Generally speaking, the characteristics of oral cancer are ulceration, tumefaction, induration and chronicity. It would take too long to detail the procedure of obtaining the specimen; but I would like to make one point in that regard before leaving the subject: The specimen for biopsy should be obtained with as little trauma as possible, to minimize the danger of spreading the disease.

I mentioned the rôle of the dentist in the rehabilitation of cancer patients. After the patient has been treated by radiation or surgery, the dentist, physician, and plastic surgeon should coöperate in prosthesis. The cured patient's readjustment to himself and to society frequently depends in large measure upon the successful restoration of function and appearance.

The follow-up of treated patients is an important aspect of any cancer control program. For various reasons, patients who have consulted physicians about suspicious lesions often fail to return for further examination or treatment. In these cases the dentist who sees the patient can render valuable assistance in many ways. He can learn, for example, what the physician advised and persuade the patient to act. He can explain why a biopsy is necessary, why the physician is the best judge as to whether the radiation should be given or an operation performed, and why delay or unskillful treatment may prove disastrous. If he learns that the patient has discontinued treatment because of alarming reactions, he can calm him and persuade him to return to his physician or hospital. One of the most important functions of the dentist in follow-up is to ascertain that the patient he referred for diagnosis has followed his advice.

So far, I have discussed in a general way the responsibility of the dentist in cancer control and some additional con-

tributions he can make to the national control program. Naturally, the question arises: By what means is he to do all this? True, the government is lending support to the dental schools, in order to provide educational advantages to the student; but what of the practising dentist? I could mention first the federal grants-in-aid to state health agencies for general health work and for cancer control. Under the latter program $2,500,000 were allocated to the states for fiscal 1949. This amount is distributed at the discretion of the state health agency, and in some instances a portion is budgeted to the state dental officer. It is my personal feeling that the state should allocate a fair proportion of these funds for the extension of educational activities directed toward the dental profession.

Among workers in state health agencies, there is growing recognition of the need for integration of cancer control activities with other operations of the agency. The cancer control officer and his staff must coöperate closely with statisticians, epidemiologists, health educators, public health nurses, state laboratories, the tuberculosis and venereal disease control divisions, the industrial hygiene department, and the dental office. Cancer, like syphilis, is a protean disease, and therefore should interest all departments on whose disciplines it impinges. There can be no doubt that the concentration of every resource upon the cancer problem is producing measurable results.

I have tried to define, in general terms, the rôle of the dentist in the national program of cancer control, and to mention some of the available resources for control activities. The National Cancer Institute solicits your assistance in this program. If the 78,000 practising dentists in the United States are informed of the problem, and prepared to meet it, they can certainly make a forceful attack on one of the gravest conditions facing the world today. It has been estimated that dentists see a fourth of the population every year—35 million patients. If those dentists remember the formula "prevention, early discovery, and adequate treatment," and see that this formula is applied, they will be amazed at the number of cancer cases they can detect, and the number of lives they can save.

The Industrial Nurse as a Health Counselor in Industry*

ETHEL C. BURGESON, R.N.

Director of Nursing Service, Sears, Roebuck and Co., Chicago, Ill.

UNTIL about two decades ago industrial nursing developed rather slowly and uncertainly. Its place in the health scene was undetermined; its principles and practices were mainly on an individual basis. Industrial nurses, isolated by the very nature of their work, were hewing out their own trails. In recent years, however, this field has gained rapid momentum. It is today a recognized agency in the program of community health and safety. It is firmly established within industry, no longer an expression of managerial philanthropy, but an integrated factor essential in production and in good human relations. Its place as a distinct branch of nursing is clearly cut.

Out of our experiences over the half century, since Ada Stewart was engaged by the Vermont Marble Company to attend its injured men, we have evolved the principles that must underlie our work. We have banded together into a national body in order to promulgate these principles. Standards for preparation for industrial nursing are emerging. Last May, nurse educators from eleven universities and colleges met with our national association here in Boston to discuss the basic curriculum. Our programs have steadily expanded as the advances of medical science, the science of human relations, and the activities of the public health field have influenced the general concepts of health work. Needless to say, in this growth health counseling has become a major factor in our objectives.

Our work began with the iodine swab in the hands of a nurse. As production methods accelerated and accidents increased, more nurses entered industry. Their tasks were mainly first aid and other ameliorative work. Costs were charged off to kindness or to dire necessity. The industrial physician was, of course, in the scene, first largely on a part-time basis, but lately more and more coming in as a full-time medical director. I shall not attempt to discuss industrial medicine here but in all that is said the presence of the physician is implied. The industrial nurse recognizes that she is a partner in the health team in which only the physician is qualified to diagnose and outline treatment.

The first major change in our work came in the passage of Workmens' Compensation Laws. This legislation, a move in the conservation of man power, reflected a growing social awareness of the value of health and freedom from needless handicap and maiming. With the passage of these laws, industrial health programs moved out of the philanthropic era into one in which they became a reckoned part of production costs. This action moved the medical department from its rather precarious place on the edge of the plant right into

* Presented at a Joint Session of the Industrial Hygiene, Engineering, and Public Health Nursing Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

the center of its being, and therefore closer to its man power.

It soon became evident that it was cheaper and better to prevent accidents than to let them happen, and as a result the safety engineer entered the scene. It became evident, too, that illness and disease, both occupational and non-occupational, were more costly in absenteeism and lowered production than were accidents. The medical programs expanded, and the industrial hygienist joined the plant group engaged in protecting the worker. In the course of events another fact became evident. The worker, away from the plant sixteen hours a day, was inseparable from the health and social conditions of his family and community. Industrial health programs and those of the community needed to be more closely related—and today we find an increasing coöperation between the two realms.

World War II marked the second major turn in industrial health programs. The economic and morale value of health work had been amply demonstrated. It was recognized as essential in conserving man power. Industry had learned during the war how to use the handicapped worker effectively. A new philosophy emerged—a recognition of the fact that few persons are physically perfect and that the skilled placement of workers according to their abilities tends to make their disabilities of lesser importance.

When health examinations were first introduced their purpose was to protect industry by excluding workers with defects. This policy cost management the use of valuable workers and it embittered labor.

We are coming now to realize that the best policy is not exclusion but proper placement. Clark Bridges in his excellent text, "Job Placement of the Physically Handicapped," says: "Every worker has some form of disability . . . but nearly every one has more ability than disability. Proper placement brings out the ability and the disability disappears." This advance in industry's employment policies has firmly established the role of health counselor for the nurse. The personnel director must have the close coöperation of the medical department to make his work effective. In the evolution of the industrial health program, the man has emerged from behind his torn hand; it is the man *and* his injury that concern us. No longer is our approach to him a philanthropic gesture but rather one of establishing sound human relations. We recognize that it is not the machine that is most important but the man behind the machine. His good will, his satisfaction with his job, his health and safety, are all prime factors in production.

As this trend increases, the responsibilities and opportunities of the industrial nurse increase. Modern mass production tends to rob a man of his individuality; the medical department helps restore it. Here he is not a number but a person, "*Mister*" or "*Joe*"; the interest is not in his productivity but in *him*. The nurse's job becomes more challenging. She uses her nursing skills; maintains smooth relationships with all departments; works in close harmony with safety engineers, industrial hygienist, personnel director; keeps adequate records for the insurance carriers; and also carries on the multitudinous tasks that come under the term of health counseling.

Health counseling in industry has many facets. It may relate to the use of chemicals, to safety devices, or to plant sanitation. It may relate to the man himself in his dietary and other similar needs. It often extends beyond factory walls to the members of his family who are reached mainly through health pamphlets carried home in his pocket. In other words, health counseling in industry is coming to mean atten-

tion to the worker's environment as well as to the man. Health education in industry, as health education in the community, requires the coöperation of the individual. The public health nurse entering the home may give nursing care or there may be no need for it; but in all instances she teaches the lessons of personal hygiene and home sanitation. She tries to remove the obstacles of ignorance, social and other problems, and physical conditions that bar the way to family coöperation in the community health program.

The industrial nurse follows these same principles. She uses the occasion of the employee's visit to the clinic to give individualized instructions relating to his particular situation. But she may also use the occasion to enlist his cooperation in a campaign against tuberculosis, veneral disease, or alcoholism. Industry will make notable contributions to our knowledge of rheumatism, arthritis, cancer and similar diseases, as its research programs gather impetus, and the nurse in her contact with the individual can be a pivotal agent in this area. As she teaches, she learns, an inevitable concomitant. Her contact with the employee is often in a health, rather than a sickness situation, as for example, care for his cut finger. The slight symptom seemingly unimportant, revealed in casual conversation or in response to skilled questioning, may have a twofold significance. It may lead to medical supervision over a serious condition but it may also furnish the researcher with valuable clues. An employee may complain of frequent headache, and examination reveals eyestrain. It is the nurse's business to learn if the trouble lies with the lighting at his post or with his disregard of the protective devices that have been provided. It is her task to support and reinforce the safety instructions given by the foreman and safety engineer.

Her relationships in the plant give her an unusual opportunity for teaching personal hygiene. She represents management, yet she is also a fellow worker. She is on both teams and she is trusted as a friend. An employee comes in for attention to a sliver. He remains to ask advice on a health problem in his home or to be instructed in some indicated lessons of personal hygiene. Visits to his home, either at his request or because he needs care, yield even greater opportunities for this instruction.

Organized health classes, well implemented with films, charts, pamphlets, are another potent source of health education. When well planned they are popular and highly productive and they are increasingly finding favor both with management and labor. Regular contributions to the plant publication by the medical department are also a common and useful device in health education. Adapted to seasonal conditions, such as a polio epidemic, they reach not only the worker but his family.

The nurse as health counselor has also an important part to play in accident prevention. Accidents, in the main, are not due to employees' physical defects. Rather they tend to occur with those who have the *habit* of accident. So well recognized is this fact that in some industries it is the policy to transfer to other jobs the worker who has had two identical, lost-time accidents. Counseling here is of paramount importance, as the nurse in conference with the employee, tries to determine the cause of his accidents and prevent their recurrence. Fatigue, home problems, maladjustments of various types all have an influence here.

The nurse's presence on the safety committee enlarges her counseling service, beyond concern with the individual, to the total plant. More and more, she is being brought into coöperation with the total plans of worker protection,

organized by the safety engineer, the industrial hygienist, and the personnel director. And more and more we are integrating the industrial health programs with those of the community. A person discovered with a medical defect during preplacement or routine examination is counseled confidentially and referred either to his personal physician or to community resources.

The nurse is conscientious about preserving the man's right to privacy, while at the same time safeguarding the health of other workers. As the community reaches into in-plant programs such as mass surveys, the counseling ability of the nurse is demonstrated in the degree of coöperation obtained from the workers.

The work of the nurse as a health counselor in industry is now unevenly developed because it is our newest phase of service. Some nurses have been unable to incorporate any of the specific activities I have outlined as health counseling. Others have been able to develop even more. These inequalities will level off as management more and more realizes the values of health counseling. The history of the development of industrial nursing gives a solid foundation for our belief that health counseling has a permanent place in the industrial health program.

New York Incorporates Its Annual Health Conference

Herman E. Hilleboe, M.D., M.P.H., New York State Commissioner of Health, announced on April 15 that New York State's Conference of Health Officers and Public Health Nurses was incorporated as the Annual Health Conference, Inc.

According to Dr. William A. Brumfield, Jr., First Deputy Health Commissioner and President of the Conference Board of Directors, the corporation was formed because of the growing importance of the conference to workers in the public health field. The conference will hold its 1949 meeting at Lake Placid, June 20–23, marking the 45th session of the conference, which attracts an attendance of more than 1,500.

Besides Dr. Brumfield, the officers include:

Vice-President — Dr. Robert H. Broad, Binghamton

Secretary—Dr. Granville W. Larimore, Albany

Treasurer—Clifford C. Shoro, Altamont

Directors—Mary E. Parker, Albany; Mary H. Parks, Albany; Elizabeth Parkhurst, New Lebanon Center; Marguerite J. Queneau, Albany; Dr. W. E. Ayling, Syracuse; Robert W. Osborn, New York City; Dr. David B. Ast, Albany; Earl Devendorf, Schenectady; Walter D. Tiedeman, Elsmere; Dr. John K. Miller, Albany.

American Academy of Pediatrics; U. S. Children's Bureau; and U. S. Public Health Service, Washington, D. C.

HEALTH services for the child of school age have tended to center at the school, first because children are concentrated there and thus can be easily reached, and second because the school situation offers an excellent opportunity for health education. In general terms, the objectives of school health services may be defined as the protection of the health of the child of school age, the development of a health consciousness for the child and his parent, the early detection of impaired health, and some sort of follow-up system to assure that defects found at the time of health examinations receive prompt attention.

In order to obtain information in this important field, a study of certain aspects of school health services has been included in the comprehensive, nation-wide study of child health services now completed by the American Academy of Pediatrics, with the cooperation of the Federal Security Agency's Public Health Service and Children's Bureau. At national, state, and local levels, facts have been gathered with a definite purpose in mind: to provide the tools with which to improve child health, not only for the country as a whole but for local communities. Therefore, certain of the data have been tabulated for each of the 3,000 counties. The findings of this study are now being reported in summary for the country as a whole[1] and in more detail for the individual states.

It should be clearly understood that the study has not attempted to gather data on all aspects of a complete school health program. Services may cover a wide range. Health education, provision for sanitary school environment, control of communicable disease are among the aspects not included in the study.

For the purposes of this paper, the following items have been selected for consideration: (1) the lack of school health services for large areas of the country and for a large proportion of the child population, (2) the division of responsibility between health and education agencies, (3) the frequency of medical examinations and the types of special tests included, and (4) the personnel active in school health programs.

LACK OF SCHOOL HEALTH SERVICES IN COUNTIES AND STATES

We have distinguished between "school medical services" and "school nursing services" and have included under the former only those in which a physician examines children at the

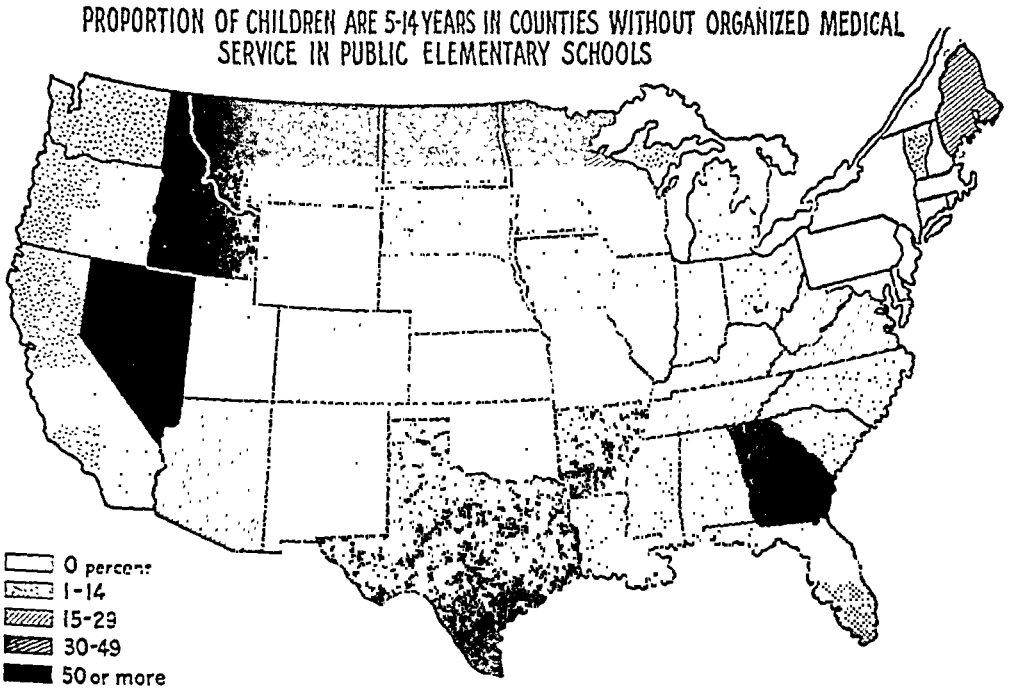
* Presented before the American School Health Association at the Seventy-sixth Annual Meeting of the American Public Health Association in Boston, Mass., November 8, 1948.

school itself for purposes other than for athletic teams.

It is recognized that in some places, instead of service being given at the school, children are referred to their own physicians or a physician who is paid by the agency responsible for the school health service. Both these methods—service provided at the school and referral to private physicians—have their proponents and advantages. We did not undertake to evaluate their comparative merits, nor did we consider it practical to include in the study of school health services the services given outside of the school.

In planning for the collection of material on school health, the number of children examined was not considered a reliable index of the amount of service. In many school health programs no individual records are kept, so that a proper count of examinations cannot be made. In this type of program, children are lined up for an "examination" which is, at best, a mere "inspection." To add a thousand such examinations from one program to 25 in another, consisting of careful and complete examinations on children selected by teacher or nurse for special care, seemed to confuse rather than clarify the issue. In some systems, nurses' or teachers' examinations are lumped in with physicians' examinations. It seemed wiser, therefore, not to attempt a count of something which is at present as heterogeneous as the school health examination.

The amount of school health service is presented in terms of the presence or absence of the service, county by county. Complete coverage has not been possible. Administration of the service is often not on a county basis but on a school district, or even individual school basis. The proportion of the child population of a county thus covered is unknown. The smallest population base with which we could work on a national basis was the county.



A county is said to be without school health service if there is not at least one public elementary school in which children are given a medical examination by a physician. For example, if a county should have 100 elementary schools and only 1 of these should have provision for health examinations, this county would be listed as having school health services. Thus the positive statement of how many counties *have* school health services is a gross over-statement. The negative statement of how many counties *do not have* school health services has more meaning.

In the United States as a whole, one-half of the counties (1,545) had no organized system of medical examinations, as defined above, in their public elementary schools in 1946. One-third of the counties had neither medical nor nursing service.

The question naturally arises as to whether the counties which lack service are mostly rural and sparsely populated areas in which there are few children and few schools. It is a fact that metropolitan areas are better covered in this respect than isolated rural areas. Of the counties, which for the purposes of this study we have classified as greater metropolitan,* there were practically none which were without some organized school medical service; of the counties which we have classified as isolated rural, 68 per cent lacked such service. But if we look at the situation from the point of view of child population, we find nearly 5,000,000 children, 5 to 15 years of age, 22 per cent of all children of this age group, in the counties without this service.

On a state by state basis there is a

* For definition of county classification as used in this study see: Hubbard, John P., Pennell, Maryland Y., and Britten, Rollo H. Health Services for the Rural Child. *J.A.M.A.* 137:337–343 (May 22), 1948.

wide range in regard to the proportion of child population in counties having no organized medical service in public elementary schools. In 8 states there were no counties which did not have at least some such service; 10 states had more than half of their counties uncovered.

ADMINISTRATION OF SCHOOL HEALTH SERVICES

The administration of school health services is a matter of controversy between health and education authorities. There is agreement on some aspects, as for example, that health education is primarily a job for education authorities and that control of communicable diseases should rest with the health agency. In order to throw some light on this issue, we included information on the administrative pattern of agencies in operation at the local level. The major difficulty in such an undertaking lies in the definition of what constitutes an agency. For education, this is usually the school authority serving a school district. The public elementary schools

TABLE 1

Counties Without Organized Medical Service in Public Elementary Schools, and Children Age 5–14 Years in Those Counties (1946)

County Group	Total Counties	Counties Without Service		Total Children	Children in Counties Without Service	
		Number	Per cent		Number	Per cent
Greater metropolitan	63	2	3	5,036,774	31,312	1

	Vermont	South Carolina	West Virginia	South Dakota
	Washington		Wisconsin	Texas
	Wyoming			

in a city are generally served by a single agency, but there may be many agencies within a county, covering individual school districts. For health, the picture is usually the reverse, a health jurisdiction frequently being made up of several counties. There is, therefore, some tendency for the number of education agencies to be multiplied and the number of health agencies to be reduced in relation to the same areas. Recognizing the limitations of the use of "agency," it is seen in Table 3 that there is a fairly even division between official education and official health agencies. About 11 per cent of the agencies have been classed as under joint administration by official education and health agencies together.

This pattern is not, of course, the same everywhere. There was a much

TABLE 3

Agencies Giving School Medical Service

greater tendency for education authorities to provide the service in metropolitan counties and for health agencies to be responsible in isolated counties.

FREQUENCY AND TYPES OF EXAMINATIONS

Another controversial subject in school health is the frequency with which examinations should be given. We undertook to determine the present practice, that is, whether the policy of the agency was to examine (1) all pupils once a year, (2) certain grades once a year, or (3) only on referrals by teacher or nurse. Though the practice was divided fairly evenly among these three patterns, emphasis appears to be given by education agencies to examining all children yearly, while the health agencies appear to be more selective in examinations.

Attention was directed specifically to the extent to which children are examined for vision, hearing, and tuberculosis. Practically all (91 per cent) of the agencies reported routine testing of vision; only about a half (54 per cent) routine and audiometer testing of hearing; and about a quarter (26 per cent) testing for tuberculosis either by x-ray or tuberculin.* It is a matter of considerable interest that official education agencies demonstrated more concern over testing for vision and hearing than the official health agencies. This is particularly true in respect to the audiometer testing; 76 per cent of the official education agencies gave routine audiometer tests in comparison with 28 per cent of the official health agencies. In respect to testing for tuberculosis, the score was low for both health and education agencies, with the former having a slight edge—28 per cent in comparison with 24 for the education agencies. There was a rather even distribution between those agencies which used x-ray examination and those which tested with tuberculin only.

* Annual testing of all pupils, certain grades, or new pupils.

PERSONNEL ACTIVE IN SCHOOL HEALTH PROGRAMS

Much of the school medical work is done by part-time physicians, either health officers (who may be full-time officers but devote only a part of that time to school work), or practising physicians who give varying proportions of their time to the schools. In adding together all the physicians giving school medical service, equal weight was given to a man devoting full time to the job and one giving one hour per week. Nor was it possible to obtain a completely unduplicated count. If a health officer or practising physician served more than one agency, he is undoubtedly counted more than once. No way out of this dilemma was found.

Of the 8,000 physicians serving in the schools about 20 per cent were health officers. The per cent of health officers working in the schools is comparatively small in metropolitan counties increasing as one goes out from these centers to the isolated rural counties. In the greater metropolitan counties 3 per cent of the physicians were health officers in comparison with 59 per cent in isolated rural counties.

About 38 per cent of the total physicians were employed by the official education agency in comparison with 31 per cent by the official health agency. The remaining one-third were employed by the official health and education agencies jointly.

Of the large majority of those physicians who were not health officers (6,390), 94 per cent were general practitioners and 4 per cent pediatricians. Thus the pediatrician plays a relatively small role in school health programs.

About 11,700 nurses gave some time to the schools, usually as a part of a general public health program. Some-

what over one-third (38 per cent) of these nurses were employed full time to work in the schools. About 40 per cent were employed by the official health agency; only slightly less being employed by the official education agency; and most of the rest being employed by official health and education agencies jointly. Again we find the southeastern region at variance with the practice throughout the country as a whole. In this region the large majority (85 per cent) of the school nurses are employed by the official health agency.

CONCLUSION

In closing, it should be pointed out that the information presented here is only in the nature of a general summary of the data collected during the course of this study in relation to school health services. More complete data will be found in the national report already referred to and in the reports of the study being published separately by the individual states.

IS AREA ERADICATION OF TUBERCULOSIS POSSIBLE?

IN a paper published in this JOURNAL in 1937, Wade Hampton Frost[1] presented a thoughtful appraisal of the question "How Much Control of Tuberculosis?" After marshalling the available evidence, he came to the conclusion that in this country we had already reached a stage at which the biological balance was against the survival of the tubercle bacillus and that eventually the mortality from this disease would be reduced to the vanishing point.

A contrary conclusion was drawn from British experience by Major Greenwood. At the end of his chapter on tuberculosis in his book *Epidemics and Crowd Diseases,* also published in 1937, he asserted that: "Without doubt it is idle to speak of the conquest of tuberculosis; tuberculosis has not been and so far as one can see never will be conquered." This opinion recently received an endorsement from Medlar[2] who was impressed with the frequency of his finding of tuberculous pulmonary lesions unrecognized during life in persons in the older age groups coming to autopsy in New York City.

The question of the validity of Frost's thesis is of great practical as well as theoretical importance. His reasoning was briefly this: There were many and sound reasons for doubting that the rapid and general decline in tuberculosis in the preceding half century had been due *principally* to the measures which had been taken for the specific purpose of preventing infection. Without question the complex group of factors included under the terms "advancing civilization and better living conditions" had played an important role. There was reason to believe, however, that the decline was due *in some part* to the direct efforts made to control the disease.

The direct attack has proved to be a more formidable undertaking than was at first realized, but in Frost's words: "If the effective control of tuberculosis required *complete* isolation of *all* open cases throughout the whole of their open stage, the present (i.e., 1937) status could not be considered encouraging, for a large proportion of such cases are discovered only after they have reached a fairly advanced stage, and the isolation even of cases known to the health authorities is probably less than 50 per cent complete. However, for the eventual eradication of tuberculosis it is not necessary that transmission be *immediately* and

completely prevented. It is necessary only that the rate of transmission be held permanently below the level at which a given number of infection-spreading (i.e., 'open') cases succeed in establishing an equivalent number (of 'open' cases) to carry on the succession. If, in the successive periods of time, the number of infectious hosts is continuously reduced, the end result of this diminishing ratio, if continued long enough, must be extermination of the tubercle bacillus."

He placed a single qualification upon his conclusion to the effect that "As to the maintenance of this balance, favorable to us, unfavorable to the tubercle bacillus, there are, of course, elements of uncertainty, among them uncertainty as to the stability of our civilization."

Only twelve years have passed—too short a period upon which to base inferences in regard to long-time trends. Yet it has been a critical period in which the very existence of civilization has been threatened. The world has undergone one of the greatest military, social, and economic upheavals in history. It is, therefore, pertinent to review the experience of this decade and inquire whether the Frost thesis is still tenable.

Despite their limitations, mortality rates provide the best available index of the biological balance in different countries over long periods of time. During the war years, mortality from tuberculosis in most of the western Europe nations involved in the conflict increased, while those countries that escaped the rigors of war were little affected. Thus, in western Germany there was a marked rise succeeded by a decline in the first two post-war years, but the rate is still higher than in 1938. In Belgium and the Netherlands, on the other hand, the rate rose sharply during the war, but by 1946 was already down to or below the 1938 level. England and France experienced moderate increases in mortality early in the war, but their rates were well below the pre-war level in 1946. In Denmark, Sweden, and Switzerland, mortality continued downward during the war. In the United States as a whole, mortality has continued to decline at approximately the same rate as that of the past quarter century. In some states and cities it has declined more rapidly than others. In only a few localities and population groups has the downward trend become definitely retarded.

It appears, therefore, that the disturbances due to the war, which were profound in some of the countries of Western Europe, have been insufficient to affect more than a temporary setback in a process of declining death rates. This lends support to the view that in certain areas of the world, where civilization is relatively advanced, the biological balance is still against survival of the tubercle bacillus.

To what extent this is due to indirect socio-economic causes or directly to control measures is a question as difficult to answer now as it was in 1937. In the United States, progress has been made in the development, and more particularly in the application, of more effective measures of control despite the war—in some respects, because of it—notably in the screening of millions of recruits by the military services, and bringing under medical care those found to have tuberculosis. Methods of treatment, of immunization, and of case finding have been improved. It is appropriate to inquire in what manner these advances may have affected the biological balance.

In the field of specific therapy the most important contribution was, of course, the discovery of streptomycin. This antibiotic is now receiving extensive clinical trial. Its values and limitations are becoming apparent. While its suppressive action has been demonstrated in tuberculous meningitis and miliary tuberculosis,

it has been somewhat disappointing in treatment of the pulmonary form of the disease, the form which is biologically essential to the dissemination of the tubercle bacillus. This experience does give hope, however, that eventually an antibiotic may be discovered and be made practicably available which will suppress growth of the microörganism in the tissues and rapidly terminate the infectious state in pulmonary tuberculosis. With such an agent, the seedbed of the disease could be more rapidly reduced.

The search for a practical and effective method of artificial immunization has progressed. The technique of production, standardization, and administration of BCG vaccine has been improved. Vaccination with this agent has had widespread trial in Europe and South America. Its safety under properly controlled conditions has been established. Critical trials (such as those reported by Holm; Ferguson; Rosenthal, Leslie, Loewinsohn; Aronson and Palmer) support the judgment that this procedure affords a considerable degree of protection against post-primary tuberculous lesions for at least a few years after vaccination. Its long-range effect in reducing the incidence of pulmonary tuberculosis has yet to be determined. For this reason, in the United States, the procedure is still under investigation, and the vaccine has not been made commercially available.

Thus, so far as public health practice in this country is concerned, the past ten years have brought forth no really new principle of prevention, although prospects for the future are bright. The main objective, as Frost stated it, is still avoidance of exposure, and the strategy is still that of a frontal assault on discoverable sources of infection.

This leads us to inquire what progress has been made in "case finding" and isolation. The tools used in diagnosis have undoubtedly been sharpened. Interpretation of the tuberculin test has been rendered more accurate by quantitative studies. Recovery and identification of the tubercle bacillus is accomplished with a greater degree of refinement by concentration, culture, or animal inoculation of gastric contents as well as sputum. The errors inherent in the reading of x-ray films have been explored and taken into account. Non-tuberculous causes of pulmonary calcification have been shown to be more frequent than was formerly supposed, at least in certain parts of this country.

Technical advances in radiography have made it practicably possible to screen large groups of the population for evidence of pulmonary pathology. Well directed "mass surveys" are undoubtedly of potential value in the early discovery of "open" cases of pulmonary tuberculosis. Their actual value depends upon the thoroughness of the follow-up and the extent to which persons with suspicious lesions are subjected to careful medical examination and observation. Further, their biological effectiveness will be determined by the adequacy of local provision for prompt medical care and the isolation of "open" cases which are discovered. Actually, this varies widely in different parts of the United States, and leaves much to be desired in many areas.

The need for sanatorium beds has by no means been satisfied everywhere. The effort to maintain hospital isolation of patients over the long periods of time required for treatment and to reduce the proportion who are discharged "against advice" is successful to a varying degree in different hospitals, but can never be completely so because of the very nature of human beings. Probably more than half of the patients who are discharged are bringing up tubercle bacilli, even though in most instances intermittently and in small numbers.

While there are still manifest deficiencies in the preventive program as it relates

to case finding and isolation, it is better than it was a decade ago. There are many and sound reasons for believing that the level of effectiveness attained in many areas is sufficient to constitute an increasingly important factor in progressively reducing the frequency of transmission from infected to non-infected individuals.

Granting continuation or strengthening of control efforts in addition to favorable socio-economic developments in a world at peace, it would seem not unreasonable to expect that the balance, favorable to us, unfavorable to the tubercle bacillus, will be maintained and that the decline in mortality from tuberculosis will be sustained, even to the point of disappearance from some areas. There is nothing in the record up to date that is inconsistent with Frost's thesis.

THE ACADEMY OF PEDIATRICS STUDY

ONE of the most outstanding public health pinnacles of 1949 is the report of the Academy of Pediatrics on Child Health Services and Pediatrics Education.[1] At a cost of one million dollars, the Academy (with the aid of the U. S. Children's Bureau, the U. S. Public Health Service, and private foundations) has completed an exhaustive and revealing survey of the actual status of health care for children in the United States. We shall present an expert review of the findings in a later issue of the JOURNAL; but it is none too soon to congratulate the Academy on a remarkable piece of public service.

Dr. Thomas Parran, Dean of the School of Public Health at Pittsburgh, pointed out at a meeting of the Academy on April 2 how significant this service has been and how naturally it grows out of the general philosophy which has governed the activities of the Academy in the past. He told the members of the Academy "because you have kept abreast of the profession and have not been among those dragged captive and shrieking behind the chariot of social progress, you are in a far better position to shape your own future than those who have been less foresighted."

The Academy, in projecting its study desired to learn whether there were a large number of children in the United States who were not receiving preventive and curative care compatible with present standards of good pediatric practice. If such were the case it sought to estimate whether the lack of adequate care was due to one or more of the following factors: "(1) parents are unable to pay for good service; (2) there is an unwillingness to use, or lack of knowledge of, available facilities; (3) services are not available where many children live; and (4) there are not enough physicians well trained in the medical care and health supervision of children, especially in rural areas."

The study demonstrates beyond question that all the factors mentioned are actually operating to the grave detriment of the health of our children. It is clear that mothers must be conscious of the need for good health care and that many are not now conscious of that need. The remedy is health education. It is clear that the care must be available where the children are; and this is not the case in our rural areas. The remedy is planning for hospitals and health centers and public financial support for their construction and maintenance. It is clear that funds must be available to pay for care; and such funds are not available for moderate

and low income groups anywhere in the United States. The remedy can only be found in prepayment of the costs of medical care on a voluntary or universal basis, or tax supported services. or a combination of the two programs. It is clear that popular interest and physical facilities and funds cannot operate successfully while there are not enough well trained physicians (not only pediatricians but general practitioners), especially in rural areas. It is to this latter problem that the Academy logically directs its major emphasis: and half the report deals with the problems of undergraduate and graduate training of physicians in this field.

The responsibility for implementing practical measures for improvement has been assigned by the Academy to a continuing Committee for the Improvement of Child Health. This report has made a case which calls for action. As Dr. Parran said, on an earlier occasion, "The Academy of Pediatrics took upon itself a heavy responsibility in making the survey; for that step inevitably obligated them to take a second and far more difficult step; viz., to use this knowledge to develop a national program of child health services."

But this obligation does not rest only on the Academy of Pediatrics. It rests on every public health worker of the country. It rests on every citizen in every state and every town. "In a nation untouched by bombs, unravaged by famine, not the prey of war-borne epidemics, three babies died for every soldier killed in combat during World War II." To quote once more from Dr. Parran, "There is a time to stand and there is a time to strike. There is a time to feel out the situation and a time to move forward. This is your hour."

THE A.S.H.A. GOES TO WAR

A LITTLE less than a year ago, Oscar R. Ewing, Federal Security Administrator and Chairman of the U. S. Interdepartmental Venereal Disease Control Committee, wrote to President P. R. Mather of the American Social Hygiene Association to request that the Association assume the following responsibilities:

"To act as advisor to Central Armed Forces Disciplinary Control Board of the National Defense Establishment in matters pertaining to civilian community education and the repression of prostitution.

"To continue and expand services to supply confidential data regarding prostitution conditions in the environs of military establishments.

"To give consideration to performing the functions of the Federal Social Protection Division, which no longer exists.

"To make available to the Armed Forces, on request, educational material and advisory services.

"To bring citizen support to good law enforcement, social treatment and individual health education through the home, the church, and the school."

The response of the A.S.H.A. was prompt and effective. Funds for the enlarged program have been obtained from the United Service Organizations. During the summer of 1948, the Association recruited, trained, and assigned to field positions a highly competent group of workers. A Washington Liaison Office was opened on September 1. By October 1, field offices were established in Chicago. Atlanta, San Antonio, and San Francisco, and the national headquarters in New York was expanded to house field representatives for the New England and Central Atlantic States. Additional scientific field assistants were assigned for

confidential studies of prostitution and related conditions. After the project had been in operation for only three months, improvements in local conditions already had been noted. In one Middle Atlantic port city of great importance to the Navy, local authorities have been stimulated to close up numerous vicious resorts frequented by servicemen. In a New England city several notorious taverns, long places of encounter of Navy men with prostitutes, have been placed "off limits" for members of the Armed Forces. A Texas city near large Army and Air Force establishments has closed most, if not all, brothels frequented by servicemen. Work is progressing in many other communities which are "leave areas" or visited by large numbers of soldiers, sailors, and airmen for any reason.

In response to a request from the Interdepartmental Committee, a team of scientific field workers spent a month in a survey of 12 Alaskan cities where prostitution was an unusually serious menace; and the results of this study will be used by the U. S. Public Health Service in prompt remedial action.

The war against venereal disease is not of the refrigerated type.

FIVE YEARS OF THE SUBCOMMITTEE ON MEDICAL CARE

IN 1944, the title of our Subcommittee on Organized Care of the Sick (a subcommittee of the C.A.P.) was changed to the Subcommittee on Medical Care. Dr. J. W. Mountin carried over as chairman; and his recent retirement[1] from the post makes it appropriate to recognize the remarkable achievements of the subcommittee during the past five years.

It was to this group that we owe the draft statement on "Medical Care in a National Health Program," adopted as an official statement of policy by the Association in the fall of 1944,[2] which remains a document of the first importance, as valid in facing the problems of 1949 as it was when first drafted.

The subsequent work of the subcommittee[3] has been no less noteworthy.

The subcommittee played a leading part in providing the staff work underlying the joint statement on "Planning for the Chronically Ill," adopted by the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association in 1947, and the statement on "Coördination of Hospitals and Health Departments" adopted by the American Hospital Association and the American Public Health Association in 1948.

Through its own staff, the subcommittee has undertaken studies of especially significant program developments, demonstrations, and trends in the field of medical care. These include a detailed study of "The Maryland Medical Care Program," and a review of the Bingham-Rockefeller program to improve the quality of medical care in Maine and Massachusetts entitled "Regionalization in New England." Two more reports, one on "The Quality of Medical Care in a National Health Program" and one on "Medical Care Activities of Full-time Health Departments" will appear in this JOURNAL during the next few months.

The vital health blood of our Association comes from the outstanding contributions of its standing committees and their subcommittees. Among these contributions those of Dr. Mountin and his associates and their keen and able staff rank very high.

LETTERS TO THE EDITOR

TO THE EDITOR:

Dr. Dublin's paper which appeared in the December issue of the *Journal*. "A Centennial of Public Health," reminded me of the even earlier legal establishment of a Board of Health for the City of Mobile than that of London. In gathering material for the January, 1939, issue of the bulletin of the Mobile County Board of Health, I ran across a record of an Act of the Legislature of Alabama, dated December 21, 1841, granting a Charter to the Mobile Medical Society. Section 6 of that Charter established the Society as a legal agency of the City of Mobile, and required it to organize a Board of Health and to procure necessary information upon the health of the City and the precautionary measures necessary to preserve the same.

We have the Minutes of the Mobile Medical Society covering its organization meeting on June 12, 1841. In these there is a Resolution to petition the Legislature at their next session for an act to incorporate the Mobile Medical Society. At an adjourned meeting on June 21, 1841, it was resolved that the President, Vice President, and Secretary of this Society constitute the Board of Health for the City of Mobile, and that the Mayor and Aldermen be requested to invest them with the proper authority of a Board of Health. On that same day the temporary Secretary of the Society wrote to the Mayor and Aldermen and advised them of the action of the Society. He gave the names of the "gentlemen composing this board" as Drs S. Mordecai, President; H. S. Levert, Vice President; Jesse Carter, Secretary. We find under date of June 22, 1841, the following Resolution by the Mayor, Aldermen, and Common Council of the City of Mobile: "that Doctrs S. Mordecai, H. S. Levert, & Jesse Carter constitute for this Municipal year a Board of Health for the City and that they be and are hereby invested with all the Authority conferred by An Ordinance constituting and establishing a Board of Health, passed on the 28th of January 1828; and that they be authorized to select from their number who shall be resident, visiting and consulting physician as required by said ordinance . . ." This was not enough, however, and there followed the State Legislature's legal establishment of the Board as referred to above.

We have not found any ordinances of the City of Mobile relative to the legally established Board of Health which indicate the exact year of their adoption. We do have, however, a volume of ordinances in force in 1858, and it contains at least three articles on health. Article I in Section 135 ordains "that it shall be the duty of the board of health in the city of Mobile, organized and appointed, under the provisions of an Act of the legislature of the State of Alabama, incorporating the 'Mobile Medical Society', passed December 21st, 1843 [the year of printing, we suppose—or a mistake] to prescribe and enforce such rules and regulations as in their opinion, may conduce to the health of the city.

"To examine into any and all cases of malignant, infectious, pestilential, and epidemic diseases, which may originate in the city, and the cause thereof.

"To enforce such measures as they may deem necessary to effect the removal of, or to check the same.

"To examine into all such nuisances

as may tend to affect or endanger the health of the city.

"And to report weekly to the mayor, aldermen, and common council of the city.

"Section 136. That if any person neglect or refuse to comply with the requisitions of the board of health, or shall prevent any member of the board from examining the yards, lots or outhouses of any person in which there is cause to believe that nuisances exist, he shall be fined ten dollars."

There are much longer articles on the subjects, "Duty of Citizens," and "Quarantine." In the article on quarantine the Board of Health was given the responsibility of advising the mayor.

Dr. Jerome Cochrane undoubtedly had the Mobile Board of Health in mind when he proposed to the Medical Association of Alabama that it offer to assume the functions of a State Board of Health.

O. L. CHASON, M.D.
Health Officer, Mobile, Ala.

March 22, 1949.

TO THE EDITOR:

Are We Not All Community Health Educators?—Education may normally be considered one of the functions of a health administrator or health director. In larger health departments, because of the multiplicity of tasks or duties which a health officer has to direct or supervise, it has become necessary to delegate to responsible assistants the direction of certain programs. Health education is one such grouping.

Whether the term "health educator" as applied to some one person on a health department staff is a "happy" designation is open to question. Actually every member of a health department staff is a health educator; otherwise he has no business being on the health department team. Thus to designate some one person *the* health educator is somewhat confusing.

The term health coördinator is sometimes applied to such a specialist, and if the functions of such a worker are mainly those of coördination, the term is not inappropriate. However, a health education specialist usually has to undertake organizing tasks. The term "community organizer," used by social workers, would seem to be particularly appropriate to one whose functions are chiefly organization functions, and organization to be effective involves coördination. But, a term such as "community health organizer" is too highfalutin a term.

Perhaps the confusion resulting in calling some one person on a health department staff *the* health educator would be largely resolved if such a person were hired as a supervisor of health education or as an administrative assistant to direct the health education activities of the staff working as a team. Certainly the division of health department activities should not be allowed to get in the way of the recognition on the part of the public that all members of a health department staff are health educators.

ALBERT R. RENWICK, DR.P.H.,
Sanitarian, District Health Unit No. 2, West Branch, Mich.

Clearing House on Public Health Salary Information and Personnel Needs

MARYLAND SAYS ITS SAY ON SALARIES

During 1948 the Maryland State Health Department, through a special salary committee, analyzed the current salaries of county health officers and bureau chiefs of the State Department of Health. The Chairman of the Committee was A. W. Hedrich, Sc.D., Chief of the Bureau of Vital Statistics. Its report was published in mimeograph form in October, 1948, and has now been made available to the Clearing House.

The report, though less than a dozen pages in length, does far more than list current salaries and recommend higher ones. At the outset the citizenry, for whom the report is obviously intended, is reminded of the eminence of Maryland's public health. The state has had full-time health service in every county for nearly a quarter of a century.

With this appeal to state pride it then produces figures to show that a public health administrator's training costs between $25,000 and $30,000, that real incomes of public health administrators have dropped by one-fifth since 1940 while those of wage earners have increased nearly one-fifth and of physicians in private practice more than one-fourth.

Maryland public health officer salaries are also compared with those in the U. S. Public Health Service and with A.P.H.A. recommendations, in each case to the disadvantage of the Maryland physicians.

The citizens are also reminded of the heavy responsibilities carried by their public health administrators—responsibilities for administering dynamic preventive health and medical care programs. "What is ordinarily termed the preventive program has by no means reached a state of perfection," says the report.

Another example of telling the citizen what will hurt him the most is a listing of some recent results in loss of staff because of better salaries elsewhere—two physicians on $5,500 salaries leaving for other states to accept positions at $8,400 and $9,350, respectively; inability to fill certain key positions at salaries offered; emergency appropriations for increased salaries to meet offers made by other communities.

The salary recommendation for public health administrators is very simple: increase both the present minimum and maximum by something over 50 per cent.

Details of the report may be requested from A. W. Hedrich, Sc.D., Director, Bureau of Vital Statistics, 2411 N. Charles St., Baltimore 18.

CANADA BRACKETS QUALIFICATIONS AND SALARIES

It will be remembered that the Canadian Public Health Association made a study of public health salaries in Canada in 1946. This was published in the *Canadian Journal of Public Health* in January, 1947, and reviewed briefly in the Clearing House *A.J.P.H.* 37:6:762 (June), 1947.

This report has been revised with 1948 data and published separately in March, 1949. It was endorsed by the Dominion Council of Health at its 56th Annual Meeting in March, 1949.

Salary recommendations are shown for the same 8 categories of public health personnel included in the earlier report, but for most categories there are

more grades of salaries and qualifications than in the earlier report.

The recommendations for each type of position are suggested for use "as a basis or guide to authorities in the preparation of salary classification and schedule." Salary recommendations do not include cost-of-living bonus, car, or room and board allowance.

The report reminds the reader that the 1946 report said "The recruitment and maintenance of an efficient, qualified professional or technical staff by official health agencies has become a major problem." It adds, "In the light of what has happened in the past two years . . . it should now read 'the recruitment and maintenance of staff is *the* major problem facing agencies today.'" "Public health is not competing successfully with other sources of professional income that are available in the United States and Canada."

The report is an excellent example of significant findings simply presented when the material is current. Too often such reports are worked over so long that they have lost their timeliness by the time they are published.

The report is available from the Canadian Public Health Association, 150 College St., Toronto 5, probably at a moderate charge. It is also published in the *Canad. J. Pub. Health*, April, 1949.

SALARIES OF STATE ADMINISTRATIVE OFFICERS

State Government for February, 1949, has a double page spread showing annual maximum salaries of state and administrative officials in each of the 48 states as of January 15, 1949. In 7 states the health officer receives the highest salary of any administrator below the governor; in 6, he is one of two or more administrators to receive the highest salary. The highway commissioner receives the highest salary in the greatest number of instances; in 10 cases he receives the highest salary, and in 8 he is one of two or more to receive the highest salary. In Iowa, for example, he receives over a third more than the next highest officer, the attorney general, and 88 per cent more than the health officer and several other administrators. In Missouri, the highway commissioner receives 17 per cent more than his nearest competitor, the conservation commissioner, and one-third more than the health officer and a number of other administrators. In New Mexico, the highway commissioner as to salary is as important as the governor, and in Wyoming, within $20 annually of being as important. In Oklahoma, the highway commissioner receives a salary more than 50 per cent higher than the next highest paid administrator, the tax commissioner, and two-thirds more than the next highest, the commissioners of health and of welfare.

It would be interesting if to this tabulation were added an analysis of some of the factors found in the Maryland study discussed above, particularly cost of training, job turnover among the various types of administrators, and relative changes in real income.

In the same issue of *State Government* is Public Health in State Government, by John D. Porterfield, M.D., Ohio State Director of Health. He ends with these words, "Studies have demonstrated that effective public health programs can save their own economic cost many times over as well as provide for the people 'a condition of physical, mental, and social well-being and not the mere absence of disease or infirmity.'" This ought to be another fruitful line of inquiry for those who must decide the relative worth of various state administrators.

State Government is the monthly organ of the Council of State Governments, 1313 East 60th Street, Chicago 37—$.50 per copy, $5 annual subscription.

Credit Lines

THE NASHOBA ASSOCIATED BOARDS OF HEALTH

Referred to as an example of "local and individual initiative" in a recent Boston editorial, the Nashoba Associated Boards of Health has been attracting wide citizen and professional interest in Massachusetts. The Association is a local health unit, organized as a demonstration 18 years ago by the Commonwealth Fund with the hope that at the end of the 5 year trial period, some of the member towns would decide to support the project. As evidence of its success 10 towns, at the close of the experiment in 1935, voted to support the Unit team of a medical director, director of nursing, sanitarian, laboratory technician, and clerks.

The Nashoba Unit suffered with personnel shortages during the war. Nine towns, however, have kept the project going even with limited services available. Their faith is now being strengthened. In 1948, a medical director and a director of nursing were employed and the sanitarian returned from his army service. The immediate objective became that of enlarging the Unit, because it was serving a population of only 16,500, far below the desired number of 35,000. A concentrated program of public relations and health education was begun in October. The joint staffs of the Unit and the District Health Office of the Massachusetts Department of Public Health worked together and have made considerable progress toward the goal. As of July 1, 1949, 25,000 citizens in the Nashoba Valley will have the protection and services of a full-time public health team of the Nashoba Associated Boards of Health. This represents a 50 per cent gain in population served.

The essence of this demonstration has been caught in a statement made by Dr. Hugh R. Leavell, President of the Massachusetts Central Health Council who said: "We feel that this demonstration of coöperation of the towns in that area toward better living, is indeed a source of great hope for the future health of our citizens."

PLANNING A MASS X-RAY PROGRAM

For nearly 4 months in the summer of 1947 an intensive chest x-ray campaign was being carried on in Minneapolis. A report of this campaign has now been published giving complete details of its organization, medical policies, public relations, community organization, records system, finances and results. The report is well illustrated, readable, and generally well produced. It is available from the Minneapolis Community-Wide Chest X-Ray Survey, 240 South Fourth Street, Minneapolis.

SPECIAL PROBLEMS OF CHILDREN

The second edition of this valuable publication, *Some Special Problems of Children, Aged 2 to 5 Years* has appeared under the auspices of the National Mental Health Foundation, Inc., Philadelphia, in association with the New York Committee on Mental Hygiene, State Charities Aid Association. This pamphlet was planned by Nina Ridenour, Ph.D., now on the staff of the National Committee for Mental Hygiene. The foreword by Robert H. Felix, M.D., of the U. S. Public Health Service and now Chief of the new Institute on Mental Hygiene, commends this pamphlet to parents and to all others who work with children "because it is a most helpful guide in

assisting us to understand and to deal with vital and everyday problems of normal children."

This pamphlet includes such problems as When a child hurts other children, When he is destructive, When he uses bad language, When he won't share, When he still sucks his thumb, When he still wets, When he masturbates. and When he has fears. This deserves a wide circulation. The sponsors can be proud of the second edition.

ACCIDENT PREVENTION THROUGH COMICS

For some 15 years the Travelers Insurance Companies have been issuing an annual booklet on accident prevention. Its 1949 edition is called "The Human Race." Its series of accident facts and figures are interlarded with pages of satirical comics—the Galahad in the drawing room who is the roadhog on the highway, the man who buys all the car gadgets ever heard of, but does nothing about defective brakes, etc., etc. Unlimited permission to reproduce and free copies are available from Travelers Insurance Companies, Hartford, Conn.

MEDICINE, LAW, AND THE FAMILY

The New York Academy of Medicine and the New York County Lawyers' Association recently coöperated in an unusual Conference on Law, Medicine and the Unstable Family. The three sessions dealt respectively with the facts of family instability, its multiple causes, and the ways in which the family can be rendered more stable.

Representatives were drawn not only from the two professions, but from sociology, education, vital statistics, family consultation, family courts and psychiatry as well. The transactions of the Conference will be published and should be requested, if desired, from the New York Academy of Medicine, 2 East 103rd St., New York 29.

SURVEY NEARLY HALF A CENTURY OLD

On April 3, the *Survey Magazine* (112 East 19 St., New York) celebrated its 40th year. Its editor, Paul Kellogg, has been associated with it since the beginning, and editor for all but the first three years. Actually the *Survey* has a longer history having existed under various names back to the 80's. The April memorial issue has articles by Howard Rusk, M.D., and Justice W. O Douglas among others. Its lead article is, "The Key to Economic Development" by Dr. J. B. Condliffe, University of California.

The *Journal* joins with many other well wishers in greeting an elder brother in the field of public health and welfare on his last lap toward the half century mark.

A WEST VIRGINIA FIRST

West Virginia in March opened its first rheumatic fever diagnostic clinic—the 26th state to do so. Located in the Marion County Health Center at Fairmont, this is a coöperative effort among the county health department, the county medical society and Fairmont General Hospital. The county health officer, A. Glenn Evans, M.D., and two members of the medical society share in the administration of the clinic; the medical society designates members to serve in the clinic for a two month period at a time, and the hospital accepts children who need hospitalization.

Children are accepted on referral from the family physician. A diagnosis with recommendations, based on physical examination, chest fluoroscopy and x-ray, urinalysis, blood count, blood sedimentation test, and electrocardiogram, is sent to the family physician.

DISCRIMINATION LESSONS STEP BY STEP

A recent resolution of the Missouri Medical Association by deleting the word "white" from its Constitution,

throws its membership open to Negro physicians. All physicians from component county medical societies are now eligible. The resolution, introduced by Park White, M.D., pediatrician of St. Louis, was passed by a vote of 60 to 16.

THE INCENTIVE OF SELF INTEREST

Pulling the heart strings is perhaps the standard method of getting money from the public for worthy causes. But the New York University-Bellevue Medical Center of New York takes another tack in its current campaign to raise more than 32 million dollars needed to complete the center.

In the March issue of its bulletin, *The Medical Advance,* it asks New York industry for at least 1½ million dollars. Its argument is a chart showing a loss of nearly 500 million dollars to New York business firms and their employees from sick absenteeism, 40 million dollars lost by 3½ million workers because of colds, a third of a 500 sample of business executives examined found with health deficiencies. This is what industry could give money for: construction and equipment of the Institute of Industrial Medicine, construction of laboratories for the study of effects on workers of chemical compounds, provision of facilities for the Laboratory of Industrial Hygiene, construction of shops for training of disabled.

Anthony J. Lanza, M.D., is chairman of the Medical Center's Institute of Medicine.

A NEW NOTE ON HEALTH INSURANCE

Perhaps the Health Insurance Plan of Greater New York is the largest of the current voluntary medical care plans now operating in the United States. Originally fathered by Mayor La Guardia, it is now in its 3rd year of operation. Basic to its methods is group practice. The contribution that its experience may have to the present discussions of voluntary versus compulsory medical care insurance is dealt with by two separate writers in the *Sunday Magazine* sections of the two leading New York City morning newspapers. In the *New York Times* of March 6 appears "The Health Issue: A Middle Course," by David Heyman, President of the Health Insurance Plan. Its thesis is: voluntary insurance for all medical care plus group practice by doctors suggested as bases for a nationwide program.

A week later, Lewis K. Hill, staff writer, wrote, "Who Will Pay the Doctor?" for *This Week* of the *New York Herald Tribune.* Here too is a suggestion that group practice is an indispensable element in medical care insurance, whether voluntary or compulsory.

DR. MOENCH PROFILED

The March, 1949, *Health Officers News Digest* of the Public Health Committee Paper Cup and Container Institute, 1790 Broadway, New York 19, has a profile of G. Frederick Moench, M.D., Director of Health and Welfare at Oak Ridge, Tenn. It is a lively story of Dr. Moench as a country doctor, health officer, active PTA worker, and now engaged in setting up a civilian public health system for what used to be a closed city like a military reservation.

IDAHO NEWS LETTER

The Idaho Public Health Association, which has been an A.P.H.A. affiliate for 10 years, has begun the publication of a monthly news letter. It is one of the few affiliates that regularly publish such a bulletin. The first issue was that of October, 1948. It has carried full news of the progress of recent health legislation in Idaho, among which is a one mill tax levy exclusively for local health purposes. The *News Letter* is available from A. W. Klotz, Secretary, Idaho Public Health Association, Box 640, Boise, Idaho, *$1 per year.*

U. S. HEALTH PICTURE REPRINTED

Anyone who has been unable to get *Guide to Health Organization in the United States,* first published by the Public Health Service in 1946, can now have it. "This panoramic view of the entire health structure of the nation" has had 1948 reprinting. Among its virtues are a bibliography and 6 appendices with a wealth of statistical information, all of it, however, still as of 1946. U. S. Gov. Ptg. Office, Washington, D. C., *20 cents.*

WORTH ACQUIRING

Where Shall We Eat? is a skit for use in training food handlers. In two acts, taking perhaps 15 minutes to play, it points out all the horrors that can be perpetuated by a careless waitress and, in contrast, the proper attention to sanitary service. A special pedagogic note is that the same waitress can be either the careless or the perfect one depending on her employer's attitude and the inservice training he provides. Prepared by the Cook County Department of Public Health from which it is available, 737 South Wolcott St., Chicago 12.

Dr. Fraud Confesses is an 8 page comic in four colors prepared for the American Cancer Society by Brevity Inc. Its first printing of 500,000 has been distributed to the 60 state and local cancer societies and is available for the public. Aimed at an adult audience, its theme is that cancer in its early stages can be cured and that the various fads and quackeries delay effective treatment and thus cause needless deaths. American Cancer Society, 47 Beaver St., New York 4.

Helping Families Plan Food Budgets has been prepared by the Bureau of Human Nutrition and Home Economics of the U. S. Department of Agriculture. It is designed as a guide for social workers, nutrition teachers, and others who are helping families get nutritionally adequate meals for the money they have to spend for food. "Better diets can mean better health for thousands," it says. Superintendent of Documents, Washington 25, D. C., *15 cents.*

Food Value Charts are 12 in number, exhibit size on heavy cardboard in pleasing maize and blue colors. These are revisions of charts first published in 1946 by the Philadelphia Child Health Society, with the coöperation of the Nutrition Division of the Pennsylvania Health Department and Philadelphia nutritionists. On the back of each chart are stated the September, 1948, revised Recommended Dietary Allowances of the Food and Nutrition Board of the National Research Council as well as facts about losses of various nutrients during cooking. Philadelphia Child Health Society, N. E. corner 7th & Delancy Streets, Philadelphia 6. Set of 12 charts, *$1.00.*

Nutrition Teaching Aids for the Use of Professional People, a set of food value charts, was originally prepared for public health workers in Cleveland. They have now been made available at cost for wider distribution. Each set includes 15 cards—3½" x 6½"—which illustrate by colored bars the comparative food value of milk and coffee, whole milk and skim milk, fish and meat, etc. Nutrition Association of Greater Cleveland, Room 1016, 1001 Huron Road, Cleveland 15, Ohio. Single sets are *30 cents;* quantities of 25 or more are *25 cents* a set.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted.

The Problem Drinker—*By Joseph Hirsh. New York: Duell, Sloan & Pearce, Inc.,* 1949. 196 pp. Price, $3.00.

A useful book. A summary of fact and opinion without novelty of information or originality of viewpoint. This well defined and much exploited segment of the alcohol problem in contemporary U.S.A. is dealt with rationally and with good purpose. Many anxious about themselves or their friends will be wise to study all the ten chapters and use appropriately the four appendices for which they will find the index quite adequate.

We have here much honest competent fact, diluted with about the same amount of emotional resistance to the practical implications of these facts.

As the genial and facile author says "science and objectivity tilt with emotion and controversy."

While disregarding all users and misusers of beverage alcohol except the minority, the problem drinker, Mr. Hirsh accepts the statement of Jellinek that "more people drinking means, of course, more chronic alcoholics." The first three chapters give some historical background and a partial story of the essentials of alcohol's effect upon man. Chapters IV, V, and VI present the familiar picture and plea for irresponsibility, of the alcohol factor, and emphasize the frequency of prior psychic abnormality of the problem drinker.

The seventh chapter, on Alcoholics Anonymous, could not be bettered if the author had written as one A.A. Present organization and accomplishment and signs of still better progress for the future are brought right up-to-date in Chapters VIII and IX. The immediacy of need of social as well as professional progress is well stressed in the final chapter.

HAVEN EMERSON

Public Health in the World Today—*Edited by James Stevens Simmons; Assistant Editor, Irene M. Kinsey; Foreword by James Bryant Conant. Cambridge, Mass.: Harvard University Press,* 1949. 332 pp. Price, $5.00.

Twenty-four distinguished contributors provide timely information in this symposium devoted to community, national, and world health. President Conant emphasizes the importance of keeping people well if we are to attain the social objectives of making the new knowledge equally effective in the lives of all the people of a nation, and discusses circumstances which caused an acceleration in the march of organized society toward increased health.

Evidence is presented dramatically by the editor to indicate how unnecessary are infections and death from smallpox, besides the accompanying hysteria and expenditures of millions of dollars. The evolution, significance and professional aspects of public health, the evaluation of medical care needs, medical education, the federal civilian, and military health and medical care services, nutrition, occupational medicine, maternal and child health, new problems of the atomic era, and international problems are among the featured topics considered by leaders fully equipped for their tasks.

Congratulations and appreciation are due for this assembly of stimulating information, with the parts so well correlated, in a well printed book which every student of medicine, of public

health, and of world affairs should read. Other professional groups will find this volume an invaluable source of authoritative statements, dedicated to a new concept of service and to a new vision of the world of the future, in which man "and all his kind can live, work, and walk with the dignity of a civilized animal in full physical, mental, and moral health."

IRA V. HISCOCK

Child Health Services and Pediatric Education. *Report of the Committee for the Study of Child Health Services. The American Academy of Pediatrics with the Coöperation of the U. S. Public Health Service and the U. S. Children's Bureau. New York: Commonwealth Fund,* 1949. 270 pp. Price, $3.50.

This report is a volume demanding the attention and study of conscientious public health workers. It disturbs complacency by its clear, persuading facts but it is encouraging in its details of "attainable levels of performance."

The study and report owe much of their strength to the interest and participation of the practising doctors of this country. The report, published by the Commonwealth Fund, is particularly notable for its concise, brief language and superior graphic presentations. Only facts are reported; recommendations and action are the responsibility of the readers and the state committees which have been formed. The method of presenting facts alone permits their analysis without the negativism often engendered by recommendations. This will not fail to arouse the urge for action among competent public health workers, however.

Three major sources of health services, private practice, hospitals, and community services, are examined in detail. Comparisons are made state by state, by regions, and by a valuable method of county groups. The selection of the critical indices for study will arouse the interest of clinicians, administrators, and all interested in evaluation.

Public health and preventive pediatrics are extensively studied. State health officers, directors of maternal and child health programs, county health officers and their staffs will not find comfort but will be challenged by the record of services we have been able to provide rural areas.

ROSCOE P. KANDLE

Personal and Community Health —*By C. E. Turner. (8th ed.) St. Louis: Mosby,* 1948. 565 pp. Price, $4.00.

Good books grow, and sometimes it takes a long time for them to ripen and mature. They are the expression of experience and their development cannot be hurried. This is especially true of textbooks. *Personal and Community Health* represents the fruit of many years of teaching health to college men and women. It is not only expressive of the knowledge necessary for good health, but also an understanding of those who must set the standards of living in the modern world. The information presented is based upon sound and progressive principles. The approach is positive, based upon conviction but accompanied by a spirit of openmindedness.

The eighth edition is an extensive work covering wide areas in both personal and community hygiene. The very difficult problem of including both fields in one book is well handled. Of necessity, some subjects are discussed but briefly. Part I, with 19 chapters, deals with personal health. Twelve chapters on community health compose part II. Good references are found at the end of each chapter. Appendix A, with a wealth of material on communicable diseases, and Appendix B, with a short but helpful discussion of disinfectants, are also included. An ex-

tremely helpful glossary to the layman concludes the work.

The book is well written and the material presented in a dignified but attractive manner. There are numerous illustrations. College teachers and students of hygiene should be interested in the volume. It is a very good book.

W. R. MORRISON

The Case of Augustus D'Esté—*Edited by Douglas Firth. New York: Macmillan*, 1948. 58 pp. 3 illus. Price, $1.75.

This little book represents a footnote in the history of medicine. It is based on a small collection of letters, diaries, account books, and other manuscripts, kept or written between 1793 and 1847 by Lady Augusta d'Ameland, wife of Prince Augustus Frederick, sixth son of George III of England, and their son Sir Augustus D'Esté. In 1940, when waste paper was being collected for conversion into pulp, these papers came to light. Much of the material had fallen prey to the gnawing criticism of rats, but what survived is of considerable interest. It contains what may be the first clinical description of disseminated sclerosis, and written by the patient. The manuscript is now in the possession of the Royal College of Physicians, London, and is reproduced by their permission. For half his life Augustus D'Esté was a victim of disseminated sclerosis, and he wrote a vivid account of it. He began to note his symptoms in 1830 and stopped in 1844. It is a record of personal experiences which could not have been suggested by any medical book, as the disease was not adequately described until twenty years after D'Esté's death in 1848. This small volume which can easily be read in one hour is recommended to all who are interested in disease from the patient's point of view and to those interested particularly in disseminated sclerosis.

GEORGE ROSEN

Proceedings of the Fourth International Congresses on Tropical Medicine and Malaria, May 10–18, 1948, Washington, D. C. *Washington: Dept. of State. U. S. Gov Ptg. Office*, 1948. 946 pp.

This volume, which has been prepared and edited by the Secretariat of the Congresses, and in collaboration with the Division of International Congresses of the U. S. Department of State, goes back to the consistent work over the years of Wilbur A. Sawyer, M.D., Secretary General, and his able associates. As Dr. Scheele, the President of the Congresses, points out in the foreword, the proceedings indicate the breadth of the program and the diversity of its subjects. There were also the intangible but nonetheless substantial values provided by the Congresses, such as the spirit of fellowship and good will which pervaded all of the activities.

The scientific work of the Congresses was divided up into sections on research and teaching institutes, on tropical climatology and physiology, on bacterial and spirochetal diseases, on virus and rickettsial diseases, and on malaria. In addition, there are reports on the official sessions and the special exercises in commemoration of the demonstration by Walter Reed of the mosquito transmission of yellow fever, as well as commemoration of the 50th anniversary of the discovery by Ronald Ross of the method of transmission of malaria.

The U. S. Department of State and the United States Government Printing Office have set through this volume a high standard for similar publications of the future.

REGINALD M. ATWATER

How to Live Longer—*By Justus J. Schifferes. New York: Dutton*, 1949. 255 pp. Price, $3.00.

This book, written in an easy-to-read style, brings together materials

giving the present status of "eleven killers of Americans: 1949." The assumption is made that a better informed public can reduce mortality rates in cardiovascular-renal diseases, cancer, accidents, tuberculosis, pneumonia, syphilis, diabetes, premature births, and suicides to the extent of 250,000 lives saved each year. The author presents statistics on trends and information as to what is now known about each "killer," including symptoms to look for, treatment, and advice as to what to do.

Although few statistical tables appear, the body of the book is given over to figures of one kind or another supporting the thesis that lives can be saved.

The advice given in each chapter falls into three major categories: (1) recognize symptoms, (2) call the physician in emergencies, for periodical examinations, and when the "little danger signals flash," and (3) assume responsibility as a citizen to see that community diagnostic and treatment facilities are available.

The chapter on "Suicide — The Ghost," is the least effective. The brief discussion of motives for suicide based on Dr. Karl Menninger's *Man Against Himself,* is so condensed that it is questionable if the reader uninitiated into psychiatric concepts can get much out of it. In the light of the complexities of the bases for suicide, one wonders if the reader will be able to function better in a "preventive" program in this area.

This reviewer does not believe with the author that "this book will hope to bring a new focus on the 'health of the nation' with greater emphasis on health education as against medical economics." In practically every instance, the author shows the need for diagnostic and treatment facilities if the education of the individual is to bear fruit in action. A combination of health education *and* medical economics is indicated.

DOROTHY B. NYSWANDER

Tests and Measurements Applied to Nursing Education — *By Hyman Krakower. New York: Putnam,* 1949. 179 pp. Price, $3.50.

Administrators, supervisors, and teachers in all fields of nursing are becoming increasingly aware of new methods of testing and measuring accomplishments, whether the accomplishments concern students' scores in classwork, relative time and costs of nursing services, or the ranking of candidates for appointive positions.

The title "Tests and Measurements Applied to Nursing Education" suggests that nurses will find useful material applicable to their problems in testing students and staff members, and the first 85 pages of this book fulfil this hope to some extent. The author covers the first steps in tabulating, classifying, and determining modes, means, medians, and percentile ranks of scores. On proceeding to more advanced calculations, however, the author's presentation becomes confused. It lacks: (1) clarity, because the basic principles are not known to nurses and are not explained, the sentence structure is frequently ambiguous and the thought underlying the statements is not clear. (For example: the first sentence of the new section explaining Binomial Expansion (page 86) reads: "Where there is one factor involved, it may take one of two forms, i.e., either happening or not happening."); (2) accuracy, because the writer tries to cover too much ground in too little space; and (3) applicability, because the purpose of the calculations is not clearly defined and the nurse is not shown how to use the results after the calculations are made.

In the main the subject matter on pages 87–138 is too advanced for those

nurses who have not had special preparation in tests and measurements, or who are not natural-born mathematicians and statisticians. Few nurses in any case would perform the calculations given in these chapters in their daily work, for example, positive and negative skewness.

Chapter X attempts to cover the subject of test construction in ten pages. This is one of the much needed techniques among teachers, but is so superficially dealt with here as to be dangerous. There is far more to test construction than a mere listing of the various forms of objective questions. (Incidentally, true-false questions are presented without any mention of the fact that this form of question is discredited for professional tests and has been discontinued by the best test technicians.) The author fails to give instructions that would aid in writing discriminating multiple-choice questions to sample knowledge and judgment and leaves out the usual warnings against the pitfalls in writing the distractors or wrong choices.

"Reliability" and "validity"—two really essential definitions in a nurse's understanding of testing—are disposed of in a few brief sentences without illustration.

There are simpler and more accurate texts for nurses who wish to become familiar with the elementary techniques of this subject. If more advanced procedures are needed, the best advice is to seek the aid of a test technician and not attempt these skilled procedures—certainly not after a mere reading of a series of mathematical steps.

DOROTHY DEMING

Odors, Physiology and Control—*By Carey P. McCord and William N. Witheridge. New York: McGraw-Hill,* 1949. 405 pp. Price, $6.50.

The recent focusing of national attention on the health and safety, as well as esthetic and economic, implications of air pollution makes this volume on the physiology and control of odors particularly timely and valuable.

This is the first time that the subject has been treated in one volume and in such an extensive manner. The index itself is particularly orderly and well developed and enables quick referral to the wealth of material presented in the 23 chapters. Beginning with the chapter on the olfactory system and describing the physiology involving chemical constitution, the book includes a detailed classification of odors and a thorough discussion of the many practices involved in the control of odors. The latter part of the book contains some very informative data on the making of an odor survey and the legal aspects of odor nuisances. The authors have also prepared a very extensive bibliography of 125 pages, grouped into a classification similar to the one employed in introducing the subject matter in the volume itself.

This volume is unique in many respects. The manner in which the data are presented not only makes it easy for the reader to understand a rather technical subject, but also adds interest. Many illustrations have been utilized, and the historical development of the problem has been traced by drawing considerably on ancient documents.

This book should be a very useful tool not only to industrial hygienists and other public health workers, but also to architects, housing authorities, city planners, and the legal profession.

J. J. BLOOMFIELD

Psychiatry for the Millions—*By Benzion Liber, M.D. New York: Frederick Fell,* 1949. 297 pp. Price, $2.95.

In this addition to the rapidly growing library of psychiatric literature for the layman, Dr. Liber favors the common sense, practical interpretation of

mental illness and its treatment. The layman will appreciate the rather down-to-earth descriptions of personality disorders and will undoubtedly find some fascination in the many case reports that are included to illustrate the various deviations from the normal. Because of a tendency to oversimplify, however, cause and effect are so often taken for granted that the reader is apt to draw unwarranted conclusions as to the fundamental and precipitating causes of mental disease. Moreover, in many instances, the impression is left that in some of the seemingly deep-seated and pervasive emotional disturbances described, a few conversations with the psychiatrist were sufficient to yield a cure. The author would not have prejudiced the case for psychotherapy had he sacrificed some of the illustrative cases for a fuller description of the dynamics of psychiatric disorders. Moreover, had he done this, the book would be more readable, since there is a tendency to repetitiveness resulting from the inclusion of so many clinical examples.

The subject matter covers a wide range of topics and includes chapters on bringing up the child, juvenile delinquency, psychosomatic medicine, sex and marital problems, alcoholism, and on war and post-war mental health. Descriptions of various types and degrees of psychoneuroses and psychoses are included and briefly discussed. The final chapter is devoted to prevention and treatment.

In this last chapter the public health worker and physician will be grateful for the frank and forthright manner with which the author discusses the current popularization of psychiatry in novels, plays, and the moving pictures, the uses and abuses of psychoanalysis, and the dangers of quackery. Greater emphasis should have been placed in this last chapter upon the need for more professional personnel, and for more facilities capable of providing programs of mental hygiene, child guidance, and research as important measures for the prevention of mental illness. Perhaps the weakest aspect of this last chapter is the section in which general recommendations for achieving mental health are offered. These recommendations consist, on the whole, of a series of "do's and don'ts" that for the modern individual are easier to read than to practise. These recommendations essentially counsel a clean healthy life and include rather dogmatic statements about the evils of constipation and of cigarette smoking for which clinical proof is as yet lacking.

This book has greater interest for the layman than for the professional worker, and its chief value resides in its avoidance of mumbo-jumbo and in the assurance that it will give to many individuals the concept that emotional instability can be treated and controlled. HENRY B. MAKOVER

Premature Infants — *By Ethel C. Dunham. Washington, D. C.: Supt. of Documents,* 1948, *Children's Bureau Publication No. 325.* 401 pp. Price, $1.25.

The fact that textbooks on this extremely important subject are few in number makes this addition to medical literature particularly welcome.

The contents of the manual are divided into two main parts: general considerations and clinical considerations.

Part I deals with the definition, diagnosis and incidence of prematurity, and the physical growth and development of premature infants. The causes and prevention of premature birth are discussed and attention is drawn to the high mortality of the premature infant. Part II covers the general care and management of premature infants, especially in relation to their physiologic handicaps and nutritional requirements. It includes sections on congenital mal-

formations, birth injury, infection, abnormal blood conditions and metabolic and nutritional disturbances.

In addition to 31 illustrations, this manual contains many tables. The subject matter is well written and attractively set out. Each section is summarized, and a good index is provided.

This is the most comprehensive work yet published on the subject. Although it gives too much detail for the average student doctor or nurse, it certainly will be agreed that no physician or nurse undertaking the care of premature infants can afford either to omit reading this manual or to omit keeping the copy constantly available for reference.

A great deal is expected from an author so experienced in her subject as Dr. Ethel C. Dunham, and this manual should meet the highest expectations.

V. MARY CROSSE

Bacterial and Mycotic Infections of Man—*Edited by René J. Dubos. Philadelphia: Lippincott,* 1948. 785 pp. Price, $5.00.

This book is the fraternal twin of *Viral and Rickettsial Infections of Man* by Rivers, et al. The editorship of Réne Dubos, another distinguished member of the Rockefeller Institute, assembles the specialized knowledge and viewpoints of 33 outstanding colleagues in research groups of the United States and Canada. The two books are very valuable in making available to clinicians and public health workers current discoveries in research. The pair are identical in handsome appearance, in freedom from typographical errors, and under the sponsorship of the National Foundation for Infantile Paralysis, in availability at extraordinarily low cost.

In keeping with the perspective of the editor, emphasis is on host-parasite relationship rather than the microörganism. The first quarter of the book is preparatory background. After Dubos and Pappenheimer discuss morphology and physiology of bacteria, Francis reviews parasitism and disease, MacLeod and Pappenheimer consider the role of the bacteria, and Francis the response of the host. Chase focuses on the interplay of host and parasite in the allergic state and Treffers in their immunological and immunochemical manifestations.

In the body of the book the specific microörganisms are described under the general headings of introduction (definition), history, morphology, cultural characteristics including nutrition and metabolism, resistance, variation, distribution and range of pathogenicity, pathogenesis, immunity, diagnosis, treatment, epidemiology and control. As a sample of famous authorities may be cited Mueller (Corynebacteria), MacLeod (Pneumococci), Nungester (Anthrax Bacillus), Meyer (Pasteurella), Conant (fungi). The concluding section contains a valuable discussion of principles of chemotherapy by Davis, a masterly condensation of the principles of epidemiology by Maxcy, and a practical consideration of identifying pathogenic bacteria by Murray and Kalz.

The material is not presented as pap. The authors strive to write in terms which all can follow, but some phases of metabolism and immunochemistry defy translation into terms with which most of us can cope. While neither conceived nor appropriate primarily as a textbook in medical bacteriology, some of the treatises are more exhaustive than those in current texts, but a few presentations tend to be cursory. Certainly study of the book will reward neophytes and veterans both of clinical medicine and of public health.

CHARLES EDWARD SMITH

The Hospital in Contemporary Life—*By Nathaniel W. Faxon, M.D. Cambridge, Mass.: Harvard University Press,* 1949. 288 pp. Price, $5.00.

Eight doctors of medicine, specialists

in different fields including an outstanding hospital director, contribute discussions in this volume on the relationship of the individual to the hospital and of the hospital to society. Much material in the book represents a digest of the literature, and credit is given to the report of the Commission on Hospital Care.

The literary style is effective, and the information presented affords an opportunity to acquire an understanding of the hospital, especially for hospital trustees, members of auxiliaries, and other non-professional hospital groups, as well as serving as a useful reference volume for students of public health, education, and social service. Perhaps a little extravagant are the publisher's note as "the most thorough-going and thought-provoking discussion . . ." and one of the author's statements concerning social forces to the effect that—"This led to the *eradication* of hospital infections. . . ."

It is gratifying to observe increasing team-play between hospitals and other official and voluntary health agencies toward a common goal of increased health, productivity, and mutual understanding. IRA V. HISCOCK

Veterans Administration Technical Bulletins. Series 10. Vol. II.—*Washington, D. C.: Veterans Administration,* 1949.

This is the second volume of a series of articles which the Veterans Administration has published and is distributing to its medical staff. The purpose is frankly educational. Brief summary articles covering a number of subjects "have the advantage of permitting more general presentation than is allowed by most journals and of providing more rapid publication than is possible in textbooks."

This volume contains a dozen articles on such subjects as "Rocky Mountain Spotted Fever," by Norman H. Topping, M.D.; "The Management of Vivax Malaria in the Veteran," by Harry Most, M.D.; "Late Residuals of Primary Coccidioidomycosis," by George C. Owen, M.D., and "Electric Shock Therapy" and "Insulin Shock Therapy" by competent authors.

Dr. Paul B. Magnuson, Chief Medical Director of the V.A., and the Administration are to be congratulated on the articles themselves, but more importantly on this type of review which must have a vital influence on medical personnel employed by the V.A.

REGINALD M. ATWATER

Microbes Militant—*By Frederick Eberson (a revision of "The Microbe's Challenge"). New York: Ronald Press,* 1948. 401 pp. Price, $4.50.

The subtitle of this book, "The Story of Modern Preventive Medicine and Control of Infectious Diseases," most adequately describes the content and should arouse the interest of the public health worker. However, when one glances over the chapter and section titles, the first reaction is one of aversion which is immediately replaced by the assumption that the book is written for purely lay readers. This is an entirely erroneous concept.

Dr. Eberson admirably and simply carries the reader through the fundamental discoveries into the more complex problems of microörganisms, such as variation and mutation, modern concepts of immunity, some of the important chemical and physiological aspects, the action of the antibiotics, the bacteriophages, and finally a discussion of a few of the major challenging problems of preventive medicine.

The book, one in the Humanizing Science Series, is written in a most interesting prose style with sufficient humor and dramatic presentation to be entertaining and relaxing. The author has attempted to solve, explain or interpret some of the baffling problems

of preventive medicine as they pertain to microbiology in the light of modern research. In some instances this has been accomplished with astounding simplicity and clarity, in other instances, present available evidence would lead some to disagree rather violently with a few of the author's interpretations.

The book cannot be recommended as an authoritative text, for which it was obviously not intended, but can be recommended for entertaining reading for all public health personnel, and would be particularly valuable for practising physicians who wish an easy review of some of the important recent developments in the field of microbiology.

LEE POWERS

A Textbook of Entomology—*By Herbert H. Ross. New York: Wiley,* 1948. 532 pp. 434 fig. Price, $6.00.

Professor Ross, in this new *Textbook of Entomology,* has succeeded admirably in his purpose to present "under one cover the fundamental aspects of entomology, organized so as to give students a general idea of the entire field," and to serve the need of the seeker for background information as well as that of the budding specialist. This he has done by emphasizing basic principles throughout and including enough pertinent detail to demonstrate those principles without burying them. His examples and illustrations are well selected, and his exposition so organized, balanced, and integrated that the whole is satisfyingly adequate. This compact and beautifully illustrated volume offers a readable, broadly conceived, and sound scientific introduction to the complexities and wonders of insect life.

The ten chapters deal with the history of entomology and its outstanding early personalities (25 pages); the classes and subclasses of Arthropoda (32 pages); external anatomy (42 pages); internal anatomy (19 pages); physiology (53 pages); the life cycle (including embryology and seasonal cycles, 47 pages); the orders of insects (with keys and references to the common families of the larger groups, 206 pages); the geological history of insects (21 pages); ecological considerations (37 pages); and control considerations (33 pages). Economic species are abundantly included as examples but are not treated individually; injury and control are simply summarized as to types and principles. Recent developments, like DDT and the use of electron microscopy, are appropriately noted. It is the only general textbook of entomology extant that adequately presents modern concepts of physiology, comparative morphology, and ecology, without at the same time slighting taxonomy.

The unavoidably arbitrary selection of material and viewpoints inherent in a simple and concise presentation of this kind has been tempered by the mature judgment born of the author's years of experience as teacher and investigator. The writing is lucid and a model of straightforward and orderly style. Minor inconsistencies and factual or typographical errors and omissions are so few as to be inconsequential in a work of such scope and merit. The format of the book is pleasingly neat, the type easily read, the figures clearly printed, the binding serviceable, and the index not exhaustive but adequate.

The book is of interest to public health workers not as a laboratory manual, but as a source of background information on arthropods in general. It can be highly recommended as an excellent entomological guidebook.

ALBERT MILLER

Physical Examination of Selective Service Registrants—*Special Monograph No. 15. Selective Service System 1947. 3 vols. Washington, D. C.: Gov. Ptg. Office,* 1948. Price, Volume I, $1.25; Volumes II and III, $1.00 each.

This is one of a series of 18 invalu-

able monographs describing the operation of the Selective Service System. As indicated by the title, this monograph deals with the medical aspects of the system. Volume I contains 16 chapters describing the origin and operation of the medical organization of Selective Service, not only in World War II, but also previous wars, with 3 chapters devoted to World War I experience, and 2 to peacetime planning and operations. The balance of the text is devoted to the second World War, special chapters dealing with medical functions, classifications, examination procedures, bases for selection, standards, analysis procedures, and administrative relationships.

The text is supplemented by 6 appendices which comprise part of Volume I and all of Volumes II and III. These appendices set forth in detail the physical standards for selection, the administrative regulations for medical examinations, the forms used and instructions for their use, and finally an entire volume of 56 tables summarizing the results of the physical examinations. These tables are broken down by regions, by states, by age and color of registrants, and by periods of time over which the system was operative. There is no breakdown by counties, this being kept for a separate series of volumes.

These volumes constitute a veritable gold mine of highly valuable information, not only on the results of the physical examinations under Selective Service, but also upon the operation of the program. Of particular interest is a brief analytical chapter entitled Lessons from Experience. The narrative portions of these volumes constitute an important record of an essential and much unappreciated part of the war record; the statistical tables will serve for a long time as one of our most valuable records of the physical status of an important segment of our nation. The Selective Service is to be commended on the prompt and careful presentation of this material in such highly usable form.

GAYLORD W. ANDERSON

Statistical Abstract of the United States, 1948 (69th ed.)—*Compiled under the Supervision of Morris H. Hansen. Washington, D. C.: Supt. of Documents, Govt. Ptg. Office,* 1948. 1,054 pp. Price, $2.75.

This is one of the books which public health statisticians should keep within handy reach. This volume, published annually, contains the most important statistics on the industrial, social, political, and economic organization of the United States.

Because the book covers such a vast scope, the data are largely restricted to those for the nation as a whole. and to some extent for states and large cities. Although information is not shown in this volume for minor civil divisions, it can readily be obtained from the sources given at the foot of each table.

This book of 1,054 pages has two purposes: (1) To serve as a convenient reference volume for quantitative summary information; (2) To serve as a guide to important sources of more detailed data. Just a glance at the titles of the 32 chapters conveys some idea of the scope of the publication.

In this 69th edition certain new subject material is presented on population forecasts; employment in the executive branch of the federal government; consumer income; current industrial production; and several other subjects.

One of the most important features of the book is the bibliography of sources of statistical data which appears at the end of the volume.

MARY DEMPSEY

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

ALCOHOL AND HUMAN AFFAIRS. Willard B. Spalding and John R. Montague. New York: World Book, 1949. 248 pp. Price, $1.64.

CHILD HEALTH SERVICES AND PEDIATRIC EDUCATION. Report of the Committee for the Study of Child Health Services. The American Academy of Pediatrics with the Coöperation of the U. S. Public Health Service and the U. S. Children's Bureau. New York: Commonwealth Fund, 1949. 270 pp. Price, $3.50.

DIAGNOSIS OF VIRAL AND RICKETTSIAL INFECTIONS. Frank L. Horsfall, Jr., Editor. New York: Columbia University Press, 1949. 153 pp. Price, $3.75.

EPIDEMIOLOGY OF HEMOLYTIC STREPTOCOCCUS, THE. Alvin F. Coburn and Donald C. Young. Baltimore: Williams & Wilkins, 1949. 216 pp. Price, $4.00.

EVALUATION OF CHEMOTHERAPEUTIC AGENTS. Colin M. MacLeod, Editor. Symposium held at the New York Academy of Medicine March 25 and 26, 1948. New York: Columbia University Press, 1949. 205 pp. Price, $4.00.

FOOD POISONING. G. M. Dack (rev. ed.). Chicago: University of Chicago Press, 1949. 170 pp. Price, $3.75.

FOR EFFECTIVE NEUTRALIZATION OF INDUSTRIAL WASTES. Philadelphia: Leeds & Northrup, 1949. 19 pp.

FUNDAMENTALS OF PULMONARY TUBERCULOSIS AND ITS COMPLICATIONS. Sponsored by the American College of Chest Physicians. Springfield, Ill.: Thomas, 1949. 470 pp. 182 illus. Price, $9.50.

GOVERNMENT OF CITIES IN THE UNITED STATES. Harold Zink (rev. ed.). New York: Macmillan, 1948. 605 pp. Price, $5.00.

GUIDING HUMAN MISFITS. Alexander Adler. New York: Philosophical Library, 1948. 112 pp. Price, $2.75.

HEALTH FILM PROGRAM FOR AMERICA, A. New York: The World Today, 1949. 28 pp. Price, $1.00.

JÁNOS, THE STORY OF A DOCTOR. John Plesch. New York: A. A. Wyn, 1949. 561 pp. Price, $5.00.

JOSEPH BOLIVAR DELEE. CRUSADING OBSTETRICIAN. Morris Fishbein with Sol Theron DeLee. New York: Dutton, 1949. 297 pp. Price, $5.00.

MANUAL OF THE INTERNATIONAL STATISTICAL CLASSIFICATION OF DISEASES, INJURIES, AND CAUSES OF DEATH. Volume I. (Sixth Revision of the International Lists of Diseases and Causes of Death.) Adopted 1948. New York: World Health Organization. 376 pp.

MEDICAL MICROBIOLOGY FOR NURSES. Erwin Neter. Philadelphia: Davis, 1949. 441 pp. Price, $4.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Most Important Cause of Death—Epidemiologic research into accident causes, and adopting remedial measures against accidents are public health responsibilities. The basis for this broad assertion will be found in these six solid papers. Read them all.

ARMSTRONG, D. B., *et al.* Accident Prevention. Pub. Health Rep. 64, 12:355 (Mar. 25), 1949.

From a World-Wide Viewpoint—Causes of disease are not solely physical or biological: they are sociological too.

Though modern, scientific medicine is 150 years old, it is only in the last fifty that this conception has begun to get a foothold. You'll like this excellent presentation of the idea.

CHISHOLM, B. Social Medicine. Scient. American 180, 4:11 (Apr.), 1949.

Fine Record—Twenty years of medical participation in Detroit's health plan find the department and the local profession viewing the results with pride. Children are immunized against diphtheria and smallpox. Two of every three have their before-school-entrance physical examinations made by a family physician.

DOUGLAS, B. H. The Private Physician and Preventive Medicine. J.A.M.A. 139, 15:977 (Apr. 9), 1949.

After One Hundred Years—Without local health services, waste of voluntary and professional effort is inevitable. The writer urges physicians to contribute time and interest to health services and learn by sharing in the problems of the officers of government.

EMERSON, H. Medicine, An Instrument of Social Progress. Michigan Alumnus Quart. Rev. LV, 16:128 (Mar. 12), 1949.

Seems Reasonable — Obstetricians, pediatricians, and public health nurses all have priceless opportunities to add to the health and happiness of parents and children. They'd do better if they worked as a professional team, says this writer who comments, "It would be nice if they could know each other"—and helpful too.

FOX, E. G. Teamwork for the Young Child. Pub. Health Nurs. 41, 4:187 (Apr.), 1949.

Fool's Paradise?—Are you one who thinks that only in Russia could a politico-scientist, a Lysenko, lay down a party-line for research? It could happen here, warns this writer, in his presidential address. If you ever look up from your own particular chore, you will want to do so now—to see what's bothering this fellow who wants to keep American science free to muddle through to great ends.

GOLDSCHMIDT, R. B. Research and Politics. Science. 109, 2827:219 (Mar. 4), 1949.

Industrial Health Is Public Health —If the last three papers fulfil the promise of the first four, this symposium on industrial health hazards and their prevention or control should prove a valuable addition to your clipping library.

GREENBURG, L. Diagnosis and Treatment of Occupational Metal Poisoning (and six related papers). J.A.M.A. 139, 13 (and 14):815 (Mar. 26), 1949.

Watching Twins Grow Old—Health workers on the shady side of—oh, let's say—fifty will find a sort of morbid contentment in the results of this study. I love this final conclusion, ". . . old age is . . . as relative in its meanings and connotations as is the faculty of being alive or the quality of being human."

KALLMANN, F. J. and SANDER, G. Twin Studies on Ageing and Longevity. J. Hered. 39, 12:349 (Dec.), 1948.

Fewer Tuberculosis Deaths, But —Mortality rates have declined more slowly in older age groups than in the younger, and the population as a whole is aging. In 1947 more than half the deaths were in people past "the vulnerable age," 15–45. This combination of statistics should give you something to ruminate over.

LEWIS, S. A. Tuberculosis Mortality in the United States, 1947. Pub. Health Rep. 64, 13:403 (Apr. 1), 1949.

Welcome, Newcomer!—It's hard to prove that diseases are spread through insanitary dishwashing practices. But who wants to eat from filthy restaurant dishes? Getting them decently clean is neither a simple nor an easy job. Methods are discussed in this

excellent paper appearing in Volume one, Number one of a promising addition to our field. We greet the newcomer.

MALLMANN, W. L. Are Restaurant Dishes a Public Health Hazard? Modern San. 1, 1:22 (May), 1949.

Sensitive Barometer—British infant death rates since the beginning of the century are plotted and analyzed in all the usual relationships, and they furnish revealing comparisons with our own. Theirs was 41 in 1947 as against our 34, but without our wide and violent regional fluctuations.

MARTIN, W. J. Infant Mortality. Brit. M. J. 4601:438 (Mar. 12), 1949.

Not Only "the Help"—Educate the public, educate the inspectors, educate the restaurant managers as well as "the help" and you can achieve good food handling practices, say these two Detroit officials.

MOLNER, J. G., and WILLSON, R. F. How Detroit Controls Food Sanitation. Modern San. 1, 1:30 (May), 1949.

Discomforts, He Calls Them—This is from the British medico who "invented" childbirth without anesthesia. "Two years ago—when I was in America—I found that the 'mind of woman' received little or no care either before or during labor. Now, however (things are different)."

READ, G. D. The Discomforts of Childbirth. Brit. M. J. 4606:651 (Apr. 16), 1949.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

AS a result of post-war developments, Turkey has come to occupy a position of considerable significance in the foreign policy of the United States. Despite this important fact, however, most Americans know little or nothing about Turkey. For this reason it may be of interest to review briefly recent Turkish activities in public health.

To understand its current problems, Turkish public health must be viewed in historical perspective. The Ottoman Empire had left the care of the public health largely to religious and other voluntary organizations. Little impression was made on the disease-ridden parts of Anatolia. The dissolution of the Ottoman Empire left a clear field for the creation of a public health organization on modern lines. When the national government was formed in Anatolia, a Ministry of Health and Social Welfare was created (1920). A campaign, almost on military lines, was organized to attack problems of disease. Since then efforts have been made to combat malaria, tuberculosis, syphilis, trachoma, and other communicable diseases rife in the villages. Special campaigns were undertaken to reduce infant mortality. As the peasants form an overwhelming proportion of the total population, rural hygiene occupies an important place in the Turkish public health program. On the whole, during the first two decades of its existence, the Turkish Republic had developed a basic health organization capable of expansion in the various branches of modern public health work.[1]

TEN YEAR HEALTH PLAN FOR TURKEY

As in so many other countries, the war interrupted these activities. In 1946, however, the government again brought the problem of public health into the foreground of public attention. A Ten Year Health Plan was prepared by the

Ministry of Health and Social Welfare and was approved by the High Council of Health after consideration in November, 1946.[2] The aims of this plan are: (1) to further and to extend the scope of preventive medicine in Turkey; (2) to provide medical facilities for the rural population; (3) to increase the present public health force and to train new personnel in modern methods; (4) to improve existing hospitals and other health institutions and to bring them up to the best modern standards; (5) to establish and to operate in seven zones or regions of the country new health institutions which will provide needed medical and social services for those areas and will form nuclei for future medical schools; and finally (6) to set up a national organization for health insurance to give practical effect to these principles.

CAMPAIGN AGAINST TUBERCULOSIS

Certain aspects of this plan have been put into operation more rapidly than others. Thus, particular attention is being paid to the control of tuberculosis. The Turkish Government sent three medical bacteriologists to Denmark to study the use of BCG in tuberculosis control.[3] As a result BCG vaccination is to be applied to new-borns and to school children. At the same time the Ministry of Health is increasing the number of beds for tuberculosis patients. In 1947, 406 beds were added and 308 more were to be added in 1948. After the completion of the National Health Plan the number of beds, which was 1,041 in 1946, should have reached a total of 5,570.[4]

In addition, considerable efforts have been made to enlist citizen participation in tuberculosis control work. The first Turkish tuberculosis association was established in Izmir in 1923, and was soon followed by those of Istanbul and a few other provinces. At the beginning of 1947 the Turkish Government organized a Tuberculosis Week. This action stimulated or brought to a focus interest in the tuberculosis problem. Within a short time the number of local tuberculosis organizations rose to 53. Early in 1948, during the second Turkish Tuberculosis Week, these associations met in Istanbul and decided to establish a National Tuberculosis Association with headquarters in Ankara. The National Association plans to undertake mass tuberculosis surveys and to assist in the application of the BCG vaccine.[5]

There is also considerable interest in public health circles in the newer methods of treating tuberculosis, particularly in the use of streptomycin.[6]

OTHER COMMUNICABLE DISEASES

Communicable diseases that are likely to break out in epidemic form have always been a problem in Turkey, and owing to the poor hygienic conditions under which a considerable segment of the population lives these still occupy a prominent place in the public health program. Typhus fever, for example, has been widespread, often in epidemic form. Though Turkey did not take an active part in World War II, an epidemic of typhus fever broke out in 1942.[7] This outbreak reached its peak about the middle of 1943. The number of cases remained approximately the same until the first half of 1945, and did not return to the pre-war level until 1947. In 1943 there were 4,142 cases while in 1947 there were 641. Most of the cases appeared during the first half of the year, especially in March. The measures taken to combat the epidemic were mass vaccination, energetic application of DDT, and requirement of early reporting of cases.

Payzin and Akyay report on a vaccine employed during a pertussis epidemic in 1948.[8] In the course of this outbreak several strains of *Hemophilus pertussis* were isolated, and a new pertussis vaccine was produced. It is reported that

the vaccine was prepared according to the method of Kendrick and Eldering, using desiccated cultures. The product was tested according to methods employed by the U. S. National Institute of Health. The vaccine was used both for prevention and treatment, and is said to have given very satisfactory results. A group of 290 children who acquired the disease were vaccinated. Of this group, 80 per cent are reported to have responded favorably, that is, the course of the disease was shortened and the interval between coughing spells was increased.

Brucellosis is another problem of concern to Turkish public health workers. Efforts to establish the prevalence of the disease and to control it have only recently been started. In Turkey, *Brucella melitensis* is reported to be the chief etiologic agent. *B. suis* is said to be absent. The diagnosis is generally made in the laboratory by means of an agglutination test. Bilal points out, however, that for a long time each Turkish laboratory had its own method and employed its own diagnostic criteria. This situation caused a great deal of confusion, and in 1943 it was decided to establish a standard agglutination test for Turkey. The method of Stableforth was ultimately proposed. A skin test has also been developed.

In 1948, S. Payzin and S. B. Golem showed that Q fever is endemic in Turkey. Various strains of *Rickettsia burneti* have been isolated in different sections of the country. It is now known that the Balkan grippe which occurred during the war was due to an agent which Caminopétros showed to be identical with *R. burneti*. Payzin has recently reported an outbreak of Q fever in an Anatolian village.[10]

From time to time there have been outbreaks of plague in Turkey. On March 15, 1947, 3 cases of bubonic plague were reported in Akçakale.[11] Within twenty-five days the number of cases increased from 3 to 19. Most of the cases were of the axillary bubonic type and 5 were septicemic. No pneumonic plague was seen. It is also reported that DDT was used as an insecticide in a 6 per cent solution in oil.

Malaria is highly endemic in Turkey and is closely related to its physical geography and particularly its climate.[12] The disease is not very prevalent on the central Anatolian plateau, but the incidence of malaria is very heavy in the coastal region. All types of malaria are present in Turkey. Spring epidemics are caused by the tertian form in almost all areas. *Vivax* paroxysms predominate in July and August, *falciparum* from the end of August to October. Depending on the locality and the season, sometimes the benign tertian form predominates and sometimes the malignant tertian form. The quartan form is encountered in various parts of the country. The chief malaria vectors in Turkey are *Anopheles maculipennis, A. elutus* and *A. superpictus. A. bifurcatus* is also reported from southern Turkey.

The Turkish Government has devoted special attention to antimalarial work. Shortages arising from the recent war compelled a temporary curtailment of the control program. In 1945, however, the Ministry of Health and Social Welfare embarked upon an Extraordinary Malaria Control Program. The number of provinces in which control activities were carried on was raised from 33 to 53 and the total of malaria control districts was increased from 18 to 32.[13]

HEALTH CENTERS FOR TURKEY

An interesting aspect of the Turkish public health program is the proposed system of health centers.[14] In its effort to place greater emphasis on preventive medicine it is planned to open health centers at a rate of one for every forty villages.[15] The health center program

will be concerned chiefly with maternal and child health, personal hygiene, prevention of communicable and epidemic disease, school health, social hygiene, narcotic control, sanitary engineering, and health education. Each health center will be expected to have medical and social records for the persons and families in the district and to follow up any condition requiring attention. Home visits will be made by visiting nurses and midwives. It is expected that when these centers are fully established it should be possible to carry out through them the campaigns against malaria, trachoma, hookworm disease, and other health problems of social concern. It is also expected that the medical and ancillary personnel will reside near the centers, so that the plans include provisions for living quarters. Public baths will also be constructed near the health centers

It is realized that a plan of this kind requires an increase in personnel. Consequently, the Ministry of Health has decided to have 100 young doctors trained annually for public health work at the School of Hygiene in Ankara. The best of these physicians will be sent to the United States for further training.

Similarly, to provide enough public health nurses seven training schools for nurses will be opened in different parts of Turkey. Other ancillary personnel is expected to be recruited from the school for sanitarians at Istanbul and from among those taking special courses in the villages.

Of interest also is the considerable emphasis on health education. For this purpose so-called health museums are to be provided These will really be centers from which health education programs will be carried out It will be worth watching this ambitious program and to observe its progress.

ADDENDUM

Our attention has been called to the fact that the two volumes—*Fiat Review of German Science 1939–1946, Bacteriology and Immunology*, and *Hygiene Part I. General Hygiene*—which were reviewed in this *Journal* in December, 1948 (pp. 1702–1703), are not available through military government channels These volumes are now available under the title *Naturforschung und Medizin in Deutschland 1939–1946* through the firm of Stechert-Hafner, Inc, 31 East 10 Street. New York City. Further information concerning these volumes may be obtained from this source.

ASSOCIATION NEWS

SEVENTY-SEVENTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
NEW YORK, N. Y., OCTOBER 24–28, 1949

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Holland M. Carter, M.D., P. O. Box 364, Madison, Fla., Director, Madison-Taylor County Health Units, State Board of Health

Eli Davis, M.D., Hadassah Medical Organizations, P. O. Box 499, Jerusalem, Israel, Director

Robert V. DiPasca, M.D., 84 Tanners Lane, Levittown, L. I., N. Y., Student, Columbia Univ. School of Public Health

Lt. Col. Thomas G. Faison, M.C., 5000 24th St., North, Arlington, Va., Medical Officer, U. S. Army

Walter P. Gardiner, M.D., 212 Audubon Blvd., New Orleans 15, La., Asst. Medical Director, Dept. of Hygiene and Child Welfare, Orleans Parish School Board

Roydon S. Gass, M.D., C.M., Ben Allen Rd., Nashville, Tenn., Director, Division of Tuberculosis Control, State Dept. of Public Health

Edwin M. Knights, Ph.D., Charles V. Chapin Hospital, Providence, R. I., Chief, Division of Sanitation, Providence Health Dept.

John P. Owen, M.D., 1880 Pacific St., San Francisco, Calif., Medical Director, American National Red Cross, Pacific Area

Robert M. Russell, M.D., Box 152, Monticello, Fla., Director, Jefferson County Health Dept.

George G. VanDyke, M.D., U. S. Quarantine Station, Rosebank, Staten Island, N. Y., Medical Consultant, International Airport Idlewild) and LaGuardia Airport

Laboratory Section

Charles Baughn, Jr., M.S.P.H., 125 N. Drexel Ave., Indianapolis, Ind., Student, Univ. of North Carolina School of Public Health

George R. Callender, M.D., Veterans Administration, Room 836, Washington 25, D. C., Chief of Pathology

Eina M. Clark, M.A., Connaught Medical Research Laboratories, Dufferin Div., Toronto, Ont., Canada, Research Asst.

Elizabeth Freeman, 601 West Jefferson St., Tallahassee, Fla., Bacteriologist, State Board of Health Laboratory

Frank C. Gettman, 465 W. 12th St., Claremont, Calif., Bacteriologist, San Bernardino County Health Dept. Laboratory

John E. Hawley, M.S., Greenwich Gardens, Apt. E-6, Old Frederick Rd., Baltimore, Md., Bacteriologist, Baltimore and Ohio Railroad

Dr. Manuel J. Machiran, Compania Ron Bacardi, S.A., Santiago, Cuba, Chief Chemist

Walter N. Mack, Ph.D., Michigan State College, Dept. of Bacteriology, East Lansing, Mich., Asst. Professor of Bacteriology

Herbert R. Morgan, M.D., Univ. of Michigan, Dept. of Epidemiology, School of Public Health, Ann Arbor, Mich., Assoc. Professor of Epidemiology

Henry T. Pringle, Pringle, S. D., Student, Colorado Agricultural and Mechanical College

Norman J. Reilly, 86 Front St., Weymouth, Mass., Chemist, Milk Laboratory, Reilly's Laboratory Service

Leon A. Spiegel, Orchard Place, Cedar Knolls, N. J., Senior Laboratory Technician, Esso Standard Oil Co. Bayway Refinery

Barbara Wells, M.S.P.H., 937 N.E. 20th St., Oklahoma City, Okla., Instructor, Preventive Medicine and Public Health, Univ. of Oklahoma Medical School

Statistics Section

Fern E. French, M.A., School of Public Health Bldg., T-4, Berkeley, Calif., Lecturer in Public Health, School of Public Health, Univ. of Berkeley

George E. Hobbs, M.D., M.P.H., Univ. of

Western Ontario, Medical School, London, Ont., Canada, Professor, Clinical Preventive Medicine and Asst. Dean

Lloyd A. Reiser, 840 S. Hobart, Los Angeles, Calif., Student, School of Public Health, Univ. of Berkeley, Berkeley, Calif.

Ardelle E. Skinner, City Registrar's Office, City Hall, Providence, R. I., Deputy Registrar

Engineering Section

Edward J. Cleary, M.S., 410 First National Bank Bldg., Cincinnati 6, Ohio, Exec. Director and Chief Engineer, Ohio River Valley Water Sanitation Commission

Thomas E. Cochran, Jr., 402 Market St., Metropolis, Ill., Sanitary Engineer, Quadri-County Health Dept.

Henry F. Eich, M.S., 848 S. Stanley Ave., Los Angeles 36, Calif., Public Health Engineer, Los Angeles City Health Dept.

Eldon C. Frye, 1718 11th Ave., Greeley, Colo., Sanitary Engineer, Weld County Health Dept.

Harry R. Holzle, 322 Indiana, Lawrence, Kans., Sanitary Engineer, Division of Sanitation, State Board of Health

Francis E. Longan, 2200 Fidelity Bldg., Kansas City 6, Mo., Public Health Engineer, Region VII, U.S.P.H.S.

William B. Loomis, 1624 Milvia St., Berkeley 9, Calif., Student, School of Public Health, Univ. of California

Thomas Lowe, Barough Hall, Roselle Park, N. J., Plumbing and Sanitary Inspector, Roselle Park Health Dept.

William M. Nash, Box 128, Dayton, Tenn., Senior Sanitarian, Rhea County Health Dept.

Philip Rosenblum, 301 S. Boyle Ave., Los Angeles, Calif., Sanitarian, Los Angeles City Health Dept.

Carl H. Scholle, D.V.M., City of Dallas, Health Dept., Dallas, Tex., Chief Veterinarian

Alfonso Villa-Acosta, Mier y Pesado 222, Mexico, D.F., Sanitary Engineering Consultant, Ministry of Hydraulic Resources

Industrial Hygiene Section

Harry J. Alvis, M.D., U.S.N. Medical Research Laboratory, New London, Conn., Student, Harvard School of Public Health

Food and Nutrition Section

Public health nursing administrator; B.S. (Education); M.A. (Public Health Nursing); 8 years' teaching; 3 years, supervisor, generalized program; for further information, please write Burneice Larson, Medical Bureau, Palmolive Building, Chicago.

NEWS FROM THE FIELD

ASSOCIATION PROPOSES NATIONAL CONFERENCE ON MEDICAL CARE

A national conference to discuss the health and medical care problems now before the nation and to be sponsored by the major professional organizations concerned, together with a broad representation of the general public, was proposed on May 6 by the American Public Health Association.

Hugh R. Leavell, M.D., Chairman of the Executive Board of the Association and Professor of Public Health Practice at the Harvard School of Public Health, Boston, upon authorization of the Executive Board, invited the American Medical Association, the American Hospital Association, and the American Public Welfare Association to join with the A.P.H.A. in sponsoring such a conference. It was expected, according to Dr. Leavell, that other professional organizations concerned, such as the American Dental Association, the nursing organizations, and other related groups might be invited. Certainly, management, labor, farmers, and other consumer groups would be included as participants "in order to obtain the widest possible representation of constructive opinion and knowledge and to assure widespread understanding and support for any decisions reached."

According to Dr. Leavell the purpose of the conference would be to determine areas of agreement and to clarify disagreements on issues of health and medical care now facing the nation. It is proposed that the conference be held during July, 1949.

Dr. Leavell pointed out that the four major organizations which had been proposed as sponsors of this conference already have reached encouraging and substantial agreement on such matters as planning for the care of the chronically ill. "It would be highly unfortunate if controversies based on differences of opinion over a few aspects of the overall problem of the nation's health should be allowed to overshadow the many points on which these groups are in basic agreement." Dr. Leavell expressed real hope that such a conference may be useful in helping to find needed answers to problems of health and medical care.

In the view of the Executive Board of the American Public Health Association, such a proposed meeting should be kept as small as possible consistent with balanced representation, and should of course communicate to the public such information as is agreeable to all parties concerned. It is the intent of the American Public Health Association that the organizations which sponsor the gathering and other participants should be free to determine the matters of agenda and procedure, according to their mutual agreement.

MORE REGIONAL CONFERENCES ON LOCAL HEALTH UNITS

The third and fourth in a series of regional conferences on local health units under the sponsorship of the National Health Council were held in Kansas City and Omaha, April 20–22 and 25–27, respectively. Each conference was attended by about 100 persons. At the first were present selected individuals interested in local health problems from Arkansas, Kansas, Louisiana, Missouri, and Oklahoma; at the second similar delegates from Iowa, Minnesota, Nebraska, North Dakota, and South Dakota.

In addition to the 2 day program heretofore planned for such conferences, one for committee discussions and reports and one for state committee dis-

cussions and reports, an additional half day was devoted to orienting delegates in the conference procedure, particularly having a sample group discussion, and to giving state groups an opportunity to organize.

Among the new developments for these conferences was the pre-conference preparation made by all 5 of the states taking part in the Kansas City Conference. Louisiana, for example, sent its 12 delegates a kit of material including facts about parish public health budgets and expenditures in relation to other services, maps of proposed health centers, a description of a local health unit in action, and other pertinent material.

In each conference, the 5 state representatives developed separate plans for extending local health services in their states. A plan common to practically all of the participating states that came out of the conference was the organization of state health councils where they do not now exist and the development of community councils. The state groups at the conference constituted themselves a nucleus for carrying out the state programs. This was most clearly evident in the Oklahoma delegation which resolved "that this group act as a nucleus for a state health council for the purpose of assisting the State Health Department in its plan for complete coverage of the state with local health units." The Iowa group adopted an 11 point program on which to begin work at a meeting of the conference group within a month. The Nebraska group committed itself to securing a state board of health for its state. The progress of the plans outlined will be followed by the National Advisory Committee on Local Health Units and reported in its *Bulletin*.

Among the features of the Kansas City Conference was a disposition to make sure that the extension of local health services would enhance and augment the services of the private physician. Here also was given a detailed discussion of the new Missouri permissive legislation, which gets around certain difficulties of the state constitution and new charter to develop the legal framework for local health services. This program was described by Chester Starr, Director of Health Services of the Missouri Farm Bureau Federation.

At the Omaha Conference some of the developments now in progress in the Missouri Valley Development were outlined by Dr. Joseph Dean of the Regional Office of the U. S. Public Health Service. The increased water available for irrigation, the increase in population, and the development of power and industrial potential will change the economy of the area. It is thus necessary to make health plans flexible enough to meet changing conditions.

At this conference there was given a brief outline of North Dakota's attempt to begin the groundwork for local health service in spite of the inability to secure full-time medical health officers. This is through the training of administrative assistants in health education techniques who would go into local areas to organize community health services, getting the support of local practising physicians. It is hoped in this way to introduce the beginnings of local health service so that it can be extended as personnel shortages abate and North Dakota salaries are increased to a competitive level.

In the planning of the two conferences, each of the 10 state health officers was asked to select a team of about 15 persons broadly representative of both lay and professional health interest. The Kansas City Conference of 101 persons met this qualification reasonably well. The 5 state teams included from 12 to 21 persons, the largest number coming from the host state, Missouri.

The Omaha Conference (because of a number of factors) was less represent-

ative either as to numbers or variety of interest. North Dakota, with the smallest population represented and the most remote from the seat of the conference, had only 2 representatives, both staff members of the State Health Department. On the other hand, 48 Nebraskans registered for the conference, the majority of them professional workers.

Thomas D. Dublin, M.D., Director of the National Health Council, presided at the meeting; Haven Emerson, M.D., gave the background address and summarized the Kansas City Conference; Roscoe P. Kandle, M.D., Field Director, American Public Health Association, gave the background address; and William R. Willard, M.D., Associate Professor of Public Health, Yale School of Medicine, summarized the Omaha Conference; John W. Ferree, M.D., and S. S. Lifson of the American Heart Association were in charge of plenary session discussions. Discussion leaders and recorders were selected from the state teams.

The following member agencies of the National Health Council had representatives at one or both conferences:

American Cancer Society, American Heart Association, American Medical Association, American Nurses' Association, American Public Health Association, American Red Cross, National Foundation for Infantile Paralysis, National Organization for Public Health Nursing, and the National Safety Council.

Detailed proceedings of the conferences are being published by the National Health Council and will be available for limited distribution.

KNUDSEN MEDAL TO DR. ROBERT A. KEHOE

At the April meeting of the American Association of Industrial Physicians and Surgeons in Detroit, Mich., the William S. Knudsen Medal was presented to Robert A. Kehoe, M.D., of the University of Cincinnati, for his work in the detection and control of lead poisoning.

The Health Achievement in Industry Award was presented to the Rome Cable Corporation of Rome, N. Y., for its recently inaugurated medical department for employees.

COLORADO REPORTS ANIMAL DISEASES

The Colorado State Department of Public Health has instituted a program of reporting animal diseases that are transmissible to human beings. Each veterinarian furnishes reports on forms designed for this purpose. Additional information may be obtained from Martin D. Baum, D.V.M., Director, Veterinary Public Health Services, State Office Building, Denver 2.

DR. HAVEN EMERSON SPEAKS ON PREVENTION OF BLINDNESS

Haven Emerson, M.D., was the principal speaker on April 27 at the annual meeting of the Maryland Society for the Prevention of Blindness in Baltimore. In discussing the relationship of voluntary and official health agencies in the program of sight conservation, he emphasized the need for well organized local health departments for maximum effectiveness of specialized sight conservation programs.

CEREBRAL PALSY RESEARCH UNIT BEGUN

The establishment of a brain registry, to collect case histories of cerebral palsy and obtain for medical study the brains of deceased victims of this disease, has been announced by the American Academy for Cerebral Palsy. These procedures will add considerably, it is believed, to present medical knowledge of cerebral palsy.

KENTUCKY MOBILE MEDICAL CLINIC

The Jefferson County Kentucky Fiscal Court has presented to the Louis-

ville-Jefferson County Board of Health the first mobile medical clinic in Kentucky, a 30 foot trailer fully equipped as a doctor's office. Its services include examinations, immunizations, child health work, and other preventive measures which are being maintained for the residents of outlying areas of the county where regular scheduled routes will be followed. A physician, a registered nurse, and a driver compose the trailer staff. During its first month of operation, the "doctormobile" brought medical service to 400 persons.

UNION LEGAL IN WASHINGTON

The Washington State Legislature has just passed Senate Bill 25 which permits cities of over 100,000 population to establish joint health departments with their counties. This legalizes the "gentleman's agreement" cooperation already in existence between Seattle and King County and between Tacoma and Pierce County. Spokane is the one remaining city of that size not yet operating jointly with its county.

100 PER CENT IN NORTH CAROLINA

The North Carolina State Health Officer, John W. R. Norton, M.D., has announced that by July 1, 1949, every county in the state will have an organized public health department. The first of the year, 96 counties were served by 70 health departments; since then the remaining 4 counties have set up or made provisions for establishing health departments.

FIRST COUNTIES IN INDIANA VOTE CONSOLIDATION THROUGH REFERENDUM

Elkhart and Clark are the first counties in Indiana to take advantage of a 1947 referendum law by which citizens may vote to establish full-time county or multi-county health departments. The recent referendum vote in the 2 counties favored the establishment of county health departments by large majorities. In Elkhart County with a population of about 75,000, this will result in the consolidation of 4 separate jurisdictions, each currently served by a part-time health officer. Clark County's department serving about 35,000 persons will consolidate two current jurisdictions with part-time health officers.

With the establishment, by resolution, of a full-time department in Kosciusko County in January, there are now 9 full-time local health departments in the state serving about 30 per cent of the population.

KANSAS'S FIRST MULTI-COUNTY UNIT

The commissioners of two Kansas counties, Butler and Greenwood, recently approved consolidations of the health services of the two counties with costs to each based on a per capita ratio of the two counties' populations. The new consolidated unit will serve a population of nearly 50,000 and will be the first multi-county unit in Kansas.

H. W. Lane, M.D., present Health Officer of Butler County, will direct the consolidated unit with headquarters at El Dorado. A subcenter will be located in Eureka of Greenwood County.

DR. W. W. FRYE BECOMES DEAN AT L. S. U. SCHOOL OF MEDICINE

The appointment of William W. Frye, M.D., Ph.D., who has been Assistant Dean at Tulane University School of Medicine and Director of the Division of Graduate Medicine, to become Dean of the Medical School at Louisiana State University, New Orleans, was recently announced to become effective as of May 1.

Dr. Frye received a Ph.D. degree at Ohio State University in 1931. He later completed the medical course at Vanderbilt University, where he was later Chairman of the Department of Preventive Medicine and Public Health. He moved to Tulane University in July,

1948, and continued his teaching and research in tropical medicine. Dr. Frye is a member of the Committee on Research and Standards of the A.P.H.A.

WASHINGTON AWARD TO JOHN L. SAVAGE

John L. Savage was recently awarded the 1949 Washington Award "for his unselfish public service devoted to the creation of monumental hydraulic structures utilizing natural resources." The Washington Award is made annually by a joint committee of the American Society of Civil Engineers, American Society of Electrical Engineers, American Society of Mining and Metallurgical Engineers, and the Western Society of Engineers.

In addition to Mr. Savage's important role in the design of many of the important United States hydraulic installations, he also designed the Yangtze River dam project in China.

A. M. A. BUREAU DIRECTOR IN GERMANY

Dr. W. W. Bauer, Chicago, Director of the American Medical Association Bureau of Health Education, sailed for Germany March 22, 1949, to consult with U. S. Military Government officials and with the German medical profession about the rehabilitation of postwar German medicine, especially with relation to public health and health education. Dr. Bauer's services have been loaned by the American Medical Association to the U. S. Department of the Army. He is scheduled to serve in Germany three months, returning by way of London, where he will spend a few days observing British health and medical systems.

PUBLIC HEALTH SPECIALTY BOARD SELECTS REPRESENTATIVES

The American Board of Preventive Medicine and Public Health, Inc., at a meeting of the Trustees in Washington, D.C., on April 25, appointed representatives of the specialty board to the Advisory Council on Medical Specialty Boards. Ernest L. Stebbins, M.D., Secretary of the American Board of Preventive Medicine and Public Health, Inc., and William P. Shepard, M.D., San Francisco, Calif., were designated to represent the board on the Advisory Council.

ANOTHER COLORADO COUNTY ORGANIZED

On January 1, 1949, the Mesa County Health Department began operating from headquarters in the Grand Junction Health Center. The Director is Margaret E. N. Beaver, M. D.; George A. Prince is sanitary engineer; Grace Larson, public health nurse supervisor. Several staff members were formerly in the Grand Junction Health Department now consolidated in the new county unit.

Mesa, with a population of about 35,000, is the 21st Colorado county to have organized public health services. Housed in the department's health center are the local cancer, tuberculosis, crippled children's, infantile paralysis societies, as well as certain activities of the county medical society.

VA AREA DIRECTORS

The following six area medical directors to supervise hospitals and other VA medical matters have been appointed:

Washington, D. C.—Delmar Goode
Atlanta, Ga.—Frank B. Brewer
Boston, Mass.—Francis B. Carroll
Fort Snelling, Minn.—Einar C. Andreassen
St. Louis, Mo.—Charles H. Beasley
San Francisco, Calif.—Cyril H. C. Francis

MINNESOTA HEALTH DAYS AGAIN

Three more of Minnesota's "Health Days" have now been held. On February 22, a group representing 8 southwestern counties met at Pipestone for the second southwestern Minnesota Health Day. A new feature of this meeting was a panel discussion arranged and presented by high school students who tossed their own questions on farm and home safety to 3 adult experts.

The first Health Day in a metropolitan area was that of Minneapolis and Hennepin County's Community Health Day on March 4. This was sponsored by the Women's Auxiliary of the Hennepin County Medical Society. Among other needs it brought to light was that of full-time health services for rural areas.

The second metropolitan Health Day was held on April 21 by St. Paul and Ramsey County. This was sponsored jointly by the Women's Auxiliary of the Ramsey County Medical Society and the St. Paul Area Public Health Council made up of 54 organizations.

Sixty of Minnesota's 87 counties have now been involved in "Health Days," the technique of that state for focusing on public health needs and the organization of community health councils and multi-county health departments.

U.S.P.H.S. ANNOUNCES ESTABLISHMENT OF MENTAL HEALTH INSTITUTE

According to an announcement by Dr. Leonard A. Scheele, Surgeon General of the U.S. Public Health Service, the National Institute of Mental Research has been established under the directorship of Dr. Robert H. Felix, who for several years has been the head of the Division of Mental Hygiene in the Service. The division has now been abolished.

The responsibilities which the division administered in the Fort Worth and Lexington Hospitals for Narcotics cases are transferred to the U.S.P.H.S. Hospital Division.

While the research center is being erected in Bethesda, Md., for the Service at a cost of some $40 million, the National Institute of Mental Research will occupy offices in the south Federal Security Building, Washington.

MINNESOTA'S NEW HEALTH UNIT LAW

The recent session of the Minnesota Legislature passed a bill authorizing county and multi-county health departments, which was signed by Governor Youngdahl on April 14. Similar bills were defeated in 1945 and the 1947 legislative sessions.

The act provides for the establishment of county or multi-county health departments either by resolution of the county commissioners or by a referendum vote.

Cities of the first and second class, of which there are 6 representing about one-third of the state's population, are exempted from the provisions of the act but may elect to join the county or multi-county health department.

According to the act all other local boards of health are divested of their current powers in areas included in a county or district health jurisdiction. There is provision for a local tax levy not exceeding one mill to support local health departments.

A provision orginally in the bill but stricken out before its final passage provided for a full-time medical health officer with special training or experience in public health administration. The law, as passed, requires only that the county or district health officer "be a doctor of medicine duly licensed and registered in the state of Minnesota." His appointment by the local board is for a 5 year term.

NEW JERSEY SURVEYS ITS HEALTH

In April the New Jersey State Health Department began a five year research survey of health practices and methods in local health departments of the state. It is planned to improve evaluation methods and to evolve a set of standards of public health practice for New Jersey based on optimal health conditions. The Commissioner of Health is required by the state reorganization law of 1947 to recommend " recognized public health activities and minimum standards of performance " for local health departments to the State Public Health

Council, which in turn is required to prescribe standards.

The survey, which operates as a part of the Bureau of Local Health Services, is made possible by a grant from the Commonwealth Fund of New York. The survey team is made up of a public health physician, public health engineer, public health nurse, statistician, and clerical workers. Staff personnel of the health department serve as expert consultants. The participation of local workers and citizens in each area is a part of the plan.

MONTANA REORGANIZES STATE BOARD OF HEALTH

A bill which had the support of the Medical and Dental Associations and the Montana Health Planning Committee, as well as the Public Health League of Montana, was passed by the Legislature and has been signed by Governor John W. Bonner.

Under its provisions, a new seven member state board of health will meet July 1, 1949, to organize. The board will be composed of 3 physicians, 1 dentist, and 3 lay members, replacing the present board made up of 5 physicians, a representative of pharmacy, and a representative of food distributors.

The new law provides that the executive officer shall be appointed by the board from persons having a degree of Doctor of Medicine and successful completion of at least 1 year of graduate study in an approved school of public health, plus at least 2 years' experience in administrative practice as a full-time public health officer. In the absence of such a qualified person the board may appoint for a period of not more than 1 year a physician with at least 5 years of active practice who shall not be eligible for reappointment.

CÖOPERATION IN DISASTER HOSPITALIZATION

The American Red Cross and the American Hospital Association have a coöperative understanding on hospitalization of disaster sufferers. This understanding has been printed for permanent reference as No. 6 in a series of preparedness leaflets, and was distributed with the January-February, 1949, issue of *Disaster*. The purpose of this understanding is to develop a plan for the coördination of hospital facilities in a disaster area so that hospital facilities may be used to the best advantage for disaster sufferers.

INDIA'S FIRST CHILD WELFARE EXHIBIT

A child welfare exhibit, presenting some aspects of children's problems all over the world, began in New Delhi, India, April 18. The first of its kind in India, the exhibition was held under the auspices of the Indian National Committee of the United Nations Appeal for Children. Invitations were sent to all foreign countries and to provincial and state governments in India.

KENTUCKY PUBLIC HEALTH ASSOCIATION

The Kentucky Public Health Association was organized at a meeting held in Louisville on March 23 to 25. At this initial meeting, the registered attendance was 685. Officers of the new society are as follows:

President—J. F. Blackerby, Director, Division of Vital Statistics, State Department of Health, Louisville

President Elect—Margaret East, Director, Division of Public Health Nursing, State Department of Health, Louisville

Vice-President—Paul Modica, Supervising Sanitarian, Lexington-Fayette County Health Department, Lexington

Secretary-Treasurer—Bruce Underwood, M.D., State Health Commissioner, Louisville

REVIEW OF SOVIET MEDICINE SUSPENDS

The American Review of Soviet Medicine has suspended publication. For the past 5 years it has served to link medical workers in Soviet Russia with others in the world. In announcing the sus-

pension, its consultant editor, Dr. Henry E. Sigerist, said "much to our regret we are unable to carry on the publication for reasons which are so obvious we need not elaborate on them." The American-Soviet Medical Society, which published the *Review*, will continue in existence and will keep its members informed of medical developments in the U.S.S.R. as opportunity develops. It will also continue the society library at the New York Academy of Medicine.

KANSAS ALSO TRAINS RURAL DOCTORS

The 1949 Kansas legislature has appropriated nearly $4 million for a three-fold program of training doctors for rural areas. The plan was worked out by the Kansas Medical School and the farm organizations gave support to it in the legislature. The plan includes:

a. An expansion of the University of Kansas Medical School graduates by 20 to 25 physicians.
b. Individual communities will set up the graduates in practice at a cost of some $15,000 which the doctors will pay back in installments.
c. The Medical School has planned a series of refresher courses to keep rural doctors abreast of medical science and technical advances.

CITY PLANNING SOUTH OF THE BORDER

A Planning Program for the Capital of Costa Rica was recently published by the Pan American Union. The study was made by Anatole A. Solow, Housing and City Planning Specialist of the Union's Labor and Social Information Division, who was formerly for two years Research Associate of the A.P.H.A.'s Committee on the Hygiene of Housing. His study of San Jose was made under a coöperative arrangement between the city, Costa Rica, and the Pan American Union.

PERSONALS

E. M. BINGHAM, M.D.,† has been appointed District Health Officer of the San Joaquin Local Health District, Stockton, Calif., succeeding JOHN J. SIPPEY, M.D., deceased. He has served for 3 years as Assistant Health Officer in San Joaquin.

ALLEN D. BRANDT, Sc.D.,* head of Bethlehem Steel Company's Industrial Hygiene Department, has been elected President-Elect of the American Industrial Hygiene Association to accede to the office of President at the next annual meeting in Chicago in 1950.

J. EDGAR CASWELL,† Acting Director of the Bureau of Public Health Education, District of Columbia, was appointed Director of the bureau succeeding MELVIN P. ISAMINGER,† deceased.

COLORADO STATE DEPARTMENT OF HEALTH, CHANGES IN PERSONNEL:

ALFRED R. MASTEN, M.D.,† has rejoined the State Department as Director of the Tuberculosis Control Section after serving in a similar capacity with the Oregon State Health Department for the last 2 years.

ROBERT D. BOTTOMS is Personnel Officer in the Business Management Division, State Department of Health.

PAUL D. BRUNS, M.D., is Obstetrical Consultant in the Maternal and Child Health Section, State Department of Public Health, and staff member of the University of Colorado Medical Center.

PAUL B. CORNELY, M.D., Dr. P.H.,* Professor of Preventive Medicine and Public Health at Howard University, Washington, D.C., has recently also become Medical Director of Freedmen's Hospital connected with the Medical School.

HERBERT R. DOMKE, M.D., M.P.H.,† presently Research Fellow in Biostatistics, Harvard School of Public Health, and formerly Chief Medical Officer of the Chicago Health Department, has been appointed Commis-

sioner of Health of St. Louis County, Missouri, effective July 1. He will also serve as Assistant Professor of Preventive Medicine of Washington University School of Medicine, St. Louis.

SAIDIE ORR DUNBAR,* for 34 years Executive Secretary of the Oregon Tuberculosis and Health Association, and past president of the General Federation of Women's Clubs, received the first annual award of the Association at its recent annual banquet, for "outstanding accomplishment" in the field of public health.

GEOFFREY EDSALL, M.D.,* has been appointed Professor of Bacteriology at Boston University Medical School effective July 1. He has been Assistant Director and recently Director of the Division of Biologic Laboratories of the Massachusetts Department of Public Health.

LEROY L. FATHERREE, M.D.,* has resigned as Health Officer of Omaha, Neb., to become Health Officer of the Will County Health Department, Illinois.

FLOYD M. FELDMANN, M.D., M.P.H.,* present Medical Director, Central Coordination and Analysis Office, and Executive Secretary, Tuberculosis Study Section, U.S. Public Health Service, will join the staff of the National Tuberculosis Association in early summer as Assistant to the Managing Director, JAMES E. PERKINS, M.D.*

EDITH M. GATES,* has accepted a position as Director of Adult Health Education with the District of Columbia Tuberculosis Association, effective May 1.

W. GEORGE GOULD,† has been appointed Field Consultant, Public Health Division of the American Heart Association, to assist the Director, JOHN W. FERREE, M.D.,* in the organization of public health programs for affiliated state and local heart associations.

JAMES C. HART, M.D.† was appointed Director of the Bureau of Preventable Diseases of the Connecticut State Department of Health, effective March 1. He has been associated with that department since 1940. He succeeds EUGENE E. LAMOUREUX, M.D.,† deceased.

EUNICE GOODMAN HOLMES has been appointed nursing supervisor of West Virginia Health Districts 5 and 6, with headquarters in the Tri-County Health Department, Martinsburg.

NORVIN C. KIEFER, M.D.,† of the U.S. Public Health Service staff has been appointed Director of the Medical Division, National Security Resources Board, succeeding JAMES A. CRABTREE, M.D., Dr.P.H.,* who is currently visiting several schools of public health. Dr. Kiefer has been Chief of the Health Emergency Planning Unit, Surgeon General's Office, U.S.P.H.S.

NELSON R. KRAEMER,† former Executive Secretary of the Hudson County (N.J.) Tuberculosis League, joined the staff of the National Tuberculosis Association on March 7 as Associate Director of Seal Sale.

VERNON W. LIPPARD, M.D., has been appointed Dean of the School of Medicine, University of Virginia, Charlottesville, succeeding H. E. JORDAN, M.D., retired.

HENRY B. MAKOVER, M.D.,* has been appointed Director of Survey of the Health Insurance Plan of Greater New York, to be responsible for conducting a study and critique of the medical services provided by the group practice units associated with the plan.

THOMAS F. MCGOUGH, M.D.,* formerly Health Commissioner, Tuscarawas County Health Department, New Philadelphia, Ohio, has accepted the

---

* Fellow, A.P.H.A.
† Member, A.P.H.A.

position of Health Officer of Alexandria, Va., effective May 15.

R. T. MEYER, M.D., recently public health officer with the American Military Government in Germany, has begun his duties as Health Officer of the Adams, Arapahoe, and Jefferson Counties Health District in Colorado.

HAROLD G. NELSON, M.D.,† Director of the Division of Epidemiology, Kansas State Board of Health, has resigned to enter private practice at the A. B. Smith Clinic in Stillwater, Okla.

OKLAHOMA: PUBLIC HEALTH NURSES ASSIGNED TO LOCAL HEALTH DEPARTMENTS

EVELYN WILSON BELLGINY, Payne County

ADA BOYD and WANDA J. REDPATH, Pittsburgh County

ELIZABETH M. JACOBS, Muskogee County succeeding HALLIE H. WILLIS, resigned to take a similar position in California.

EDITH DICKSON,† Comanche County.

DONALD E. PORTER,† previously assistant to the statistician GODIAS J. DROLET,* has been named secretary of the tuberculosis division of the New York Tuberculosis and Health Association to have charge of all x-ray activities of the Association in Manhattan, including industrial and community case finding surveys, and to serve also with the Tuberculosis Sanatorium Conference of Metropolitan New York.

GEOFFREY W. RAKE, M.D., Head of the Division of Microbiology, has been appointed Director of the Squibb Institute for Medical Research to succeed JAMES A. SHANNON, M.D., resigned to become Associate Director in charge of research, National Heart Institute.

JEANNETTE ROSENSTOCK,* Director of Nursing Service in the Topeka-Shawnee County Health Department, Kansas, on May 1 became Assistant Chief in Administration in the Bureau of Public Nursing, Pittsburgh, Pa.

CATHRYN C. ROTONDON, M.D., began her work as Director of the Division of Maternal and Child Health of the Kentucky State Health Department on March 14, replacing ALICE D. CHENOWETH, M.D.,* who is now with the U.S. Children's Bureau.

EDWARD M. THOMPSON, M.D.,† formerly with Lexington-Fayette County Health Department of Kentucky is now Health Officer of the DeWitt-Piatt County Health Unit in Illinois.

VIRGINIA STATE HEALTH DEPARTMENT —NEW HEALTH OFFICERS ASSIGNED TO LOCAL HEALTH DISTRICTS:

J. E. MALCOMSON, M.D., Halifax County

WILLIAM D. ANDERSON, M.D., Russell-Wise

E. D. HARDIN, M.D.,† formerly in Pittsylvania, now located in Page-Warren-Shenandoah

ALICE WATERHOUSE, M.D.,† a Health Officer in the New York City Department of Health, has been named Director of the newly created Bureau of Adult Hygiene.

WILHELMINA L. WHISNER,† has been appointed teaching supervisor in the Kanawha-Charleston Health Department, West Virginia.

Deaths

F. A. BABOUR,* Consulting Hydraulic and Sanitary Engineer, Boston, Mass. (Engineering Section).

CHARLES J. BALL,† Director, Bureau of Sanitation, New Orleans, La., Health Department (Health Officers Section).

JOE RAINEY CLEMMONS, M.D.,† former Medical Director and Executive Vice-President of Roosevelt Hospital, New York, died April 2 at the age of 52, after a long illness (Unaffiliated).

---

* Fellow, A.P.H.A.
† Member, A.P.H.A.

GILBERT COTTAM, M.D.,* died March 4 at the age of 75 (Health Officers Section).

ALFRED LEE FRANKLIN, M.D., 29 year old research scientist in the Nutrition and Physiology Research Department of the Lederle Laboratories Division of American Cyanamid Company, died recently of chronic nephritis at Cedars of Lebanon Hospital, Los Angeles, Calif.

MELVIN PRICE ISAMINGER, Dr.P.H.,† died recently after a long illness. He was Director of the District of Columbia Health Department's Bureau of Public Health Information (Public Health Education Section).

GEORGE F. MANGONE, M.D.,† Health Officer, Department of Health, Union City, N. J. (Health Officers Section).

CARL E. MCCOMBS, M.D.,* died May 6 after a long illness. He retired last year as a staff-member of the Institute of Public Administration, New York (Public Health Education Section).

LEOPOLD M. ROHRA, M.D., died April 6 at the age of 62. Dr. Rohr was a medical practitioner in New York for nearly 40 years and was well known for his work for public health.

FREDERICK F. TISDALL, M.D.,† Assistant Professor of Pediatrics, University of Toronto, Canada (Maternal and Child Health Section).

CAMILLO E. VOLINI, M.D.,† Superintendent of Clinics, Municipal Tuberculosis Sanitorium, Chicago, Ill., died June 28, 1948 (Health Officers Section).

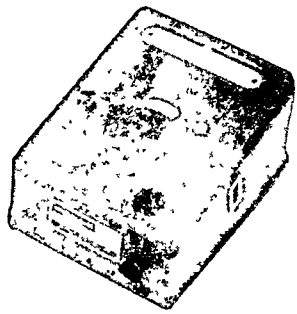
The Model 7 Photo-Nephelometer is a new Coleman instrument that saves time. It utilizes proven principles in a new way, offering analysts the inherent speed and convenience of Nephelometry but adding modern instrumentation and standards to guarantee consistent precision.

MEASURES HAZE ACCURATELY IN:—

★ beverages ★ serums ★ boiler condensates
★ oils ★ plating baths ★ cultures ★ plastics



PROVED INVALUABLE IN:—

★ water treatment ★ confectionery ★ whiskey
★ tanning ★ filtration ★ bacterial growth studies ★ flotation control

The Coleman Photo-Nephelometer is designed for precision measurements at invisible suspension levels. It insures exact and reproducible turbidity measurements of nearly all liquids.

The instrument is strictly linear in haze response. Its sensitivity allows analysis at the very low concentrations where "haze" chemistry is also linear. Consequently, data are usually quantitatively linear thru almost three orders of magnitude! These characteristics also allow *macro determinations of micro quantities*, offering a simplicity and certainty too frequently lacking in present micro technics.

Write for Bulletin B-213

Five overlapping Coleman Standards cover the entire haze range—offering for the first time, an exact, coherent, stable, and universally applicable system for expressing haze numerically—in terms understandable and reproducible between instruments and laboratories, independent of time.

4789 Coleman Photo-Nephelometer, complete with constant voltage transformer with connecting cables, immersion well, mounting pads, scale panel, plastic light shield, and operating directions.

The B-K PR PLAN stands for better patron relations between farmer and dairy plant. As the basis for this, a complete program has been set up by the makers of B-K to help the farmer produce top quality milk through a definite and efficient dairy sanitation program.

This B-K PR PLAN offers the dairy farmer . . . through his fieldman . . . informative films, recordings, literature and other educational material . . . that directs the farmer's attention to the need for positive dairy sanitation.

You can depend on the authenticity and accuracy of the material used in this B-K PR PLAN, for it has been carefully prepared by the makers of B-K Products—the backbone of many quality milk programs. Find out more about the B-K PR PLAN and how you can play a part . . . we'll send full details on request. Write: Dept. PR, B-K Division, Pennsylvania Salt Manufacturing Company, 1000 Widener Building, Philadelphia 7, Pa.

The "Shattuck Report"

Republished for the first time!

"One of the most remarkable documents—perhaps the most significant single document in the history of Public Health."
C.-E. Amory Winslow

Report of the Sanitary Commission of Massachusetts: 1850

By Lemuel Shattuck and Others

THIS is the famous first general plan for the promotion of public health to be presented to an American governmental body, and its influence over the whole field ever since that time can hardly be exaggerated. The "Shattuck Report" made fifty specific recommendations regarding sanitation, recording of vital statistics, protection of school children, medical research, nurses' training, slum clearance, and other problems vital to the increase of the mean expectation of life in the United States. Its first proposal was for the creation of state and local boards of health in an era when such state commissions were non-existent.

Lemuel Shattuck (1793–1859) was a business man—a bookseller and publisher—whose important public services include plans for the recording and preservation of public documents, and the establishment (due to his efforts) of the Massachusetts System for the registration of births, deaths, and marriages. In 1839 he was one of the founders of the American Statistical Association.

Now republished for the first time since its original release in 1850, this facsimile edition of the "Shattuck Report" again makes it available to everyone interested in medicine, public health, or the vital statistics and social conditions of the mid-nineteenth century. It is sponsored by the American Public Health Association, the Massachusetts Public Health Association, the Harvard Graduate School of Public Health, the Massachusetts Department of Public Health, and the Boston Health Department. *ix + 321 pages, $4.50*

PROTECTS CONSUMERS AGAINST *THEMSELVES!*

Milk contamination can too often occur in the hands of the ultimate consumer. Fork-prying and finger-pushing methods of opening bottles and careless discarding of a separate hood—common in both home and restaurant—constitute real threats to milk purity.

Genuine snug-fitting Seal-Kaps minimize these dangers. Seal-Kaps come off with a simple twisting motion. No need to pry or push. And they *snap back on* as often as necessary to protect securely the pouring lip until the last drop is used. There is no separate hood to discard, because Seal-Kap is disc and hood *in one.* And since it's so convenient to use, consumers automatically enjoy a superior protection—protection *against themselves!*

AMERICAN SEAL-KAP CORP.

Meat and the Management Of Macrocytic Anemias

A recent clinical study* on the efficacy of vitamin B_{12} in macrocytic anemias emphasizes the value of a diet high in complete protein in the general management of these conditions.

In addition to specific antianemia therapy "a diet rich in animal protein" is recommended as one of the principles of treatment in pernicious and related macrocytic anemias.

Meat deserves a prominent place in the dietary of these anemias. It is an outstanding source of complete protein, providing all the amino acids essential for blood formation and tissue repair. In addition to its notably high content of complete protein, meat is one of man's best natural sources of B-complex vitamins and iron.

The excellent digestibility of meat makes possible its use twice or more times daily when required by dietary demands.

DIFCO

BACTO-THROMBOPLASTIN

for Prothrombin Time Determinations of Blood

A *stablized desiccated rabbit brain substance of uniformly high* thromboplastic potency applicable to all prothrombin time procedures using blood or whole or diluted plasmas. It is especially recommended for use in following prothrombin activity in patients on dicumarol therapy.

Bacto-Thromboplastin is distributed in ampuls containing sufficient material for the preparation of approximately 3 ml. of thromboplastin extract. It is available in packages of six ampuls.

BACTO-CEPHALIN CHOLESTEROL ANTIGEN

for the Hanger Flocculation Test

An approved stable reagent for use in the Hanger Flocculation Test for determining the index of disturbance of the liver parenchyma.

Bacto-Cephalin Cholesterol Antigen is distributed in packages of six units, each unit containing the required amount of reagent to prepare 5 ml. of stock ether antigen solution and 150 ml. of final test antigen.

BACTO-THYMOL TURBIDITY REAGENT

and KINGSBURY STANDARDS

for the Maclagan Thymol Turbidity Test

A standardized buffered thymol reagent recommended for use in the Maclagan Thymol Turbidity Test for indicating hepatic parenchymal impairment. Kingsbury Standards are also available.

Bacto-Thymol Turbidity Reagent is distributed in packages of six bottles of 25 ml. each.

PHENOLSULFONPHTHALEIN AMPULS, DIFCO

for Renal Function Test

A sterile aqueous solution of the monosodium salt of Phenolsulfonphthalein standardized for parenteral use in renal function determinations. It is available in packages of 10 ampuls of 1 ml. each.

Long lines of black ants attracted to madhumeha, "honey urine," led the ancient Hindu wise men to observe and recognize diabetic urine, which they described as "astringent, sweet, white and sharp." Avid insects became an acknowledged means of diagnosis. Almost equally primitive methods of urine-sugar detection remained in effect for a score or more of centuries, until modern copper reduction tests were perfected, refined and simplified.

Simplest of all today is the reliable *Ames* tablet method, performed in a matter of seconds. Urine-sugar levels are determined by direct, easily-learned steps. The use of *Clinitest* (Brand) reagent tablets has eliminated the inconvenience of external heating. Interpretation of routine urine-sugar testing follows readily from color scale comparison.

A-2271

for V.D.R.L. (Cardiolipin) test for syphilis
Boerner-Jones-Luken, Mazzini, Kline Tests
Blood banking—Other mixing operations

YANKEE ROTATORS

Yankee Rotators simulate hand mixing by imparting a gentle circular motion in the horizontal plane. They are designed for micro slide agglutination tests, blood typing and grouping tests, mixing solutions in flasks, beakers, etc. and many other procedures where gentle continuous mixing is indicated. Three types are available, to meet the requirements of different procedures.

A-2271 and A-2276, designed for the V.D.R.L. (Cardiolipin) test for syphilis, rotate at the required rate of 180 RPM.

A-2270 and A-2275, for the Boerner-Jones-Luken, Mazzini, Kline and other micro slide agglutination tests, rotate at 130 RPM.

A-2280, for use in blood banking to mix the anti-coagulant with the donor's blood as it is being received, rotates at 100 RPM.

A-2270 and A-2271 accommodate twelve 3 x 2" concavity slides or a number of large containers. A-2275 and A-2276 accommodate six 3 x 2" concavity slides or one large container. A-2280 accommodates one 600 or 750 ml. plasma bottle. All models except A-2280 have a built-in timer which can be set to shut the motor off automatically after a 2 to 5 minute mixing period; the timer can be cut out of the circuit when continuous operation is desired.

A-2270 Yankee Rotator, 11 x 11" platform, 130 RPM, with automatic timer; for 110 v., 60 cycle AC.....Each $52.50

A-2271 Yankee Rotator, 11 x 11" platform, 180 RPM, for the V.D.R.L. (Cardiolipin) test for syphilis; with automatic timer; for 110 v., 60 cycle AC.....Each $52.50

A-2275 Yankee Rotator, 9 x 9" platform, 130 RPM, with automatic timer; for 110 v., 60 cycle AC..... Each $45.00

A-2276 Yankee Rotator, 9 x 9" platform, 180 RPM, for the V.D.R.L. (Cardiolipin) test for syphilis; with automatic timer; for 110 v., 60 cycle AC.....Each $45.00

A-2280 Yankee Donor Blood Rotator, 9 x 9" platform, 100 RPM, without automatic timer; for 110 v., 60 cycle AC. .....Each $40.00

An *itch* stopped this machine

It might have been the new cutting oil that gave Joe the rash. Maybe the picnic ground last Sunday was dotted with pretty green poison ivy plants. Or maybe Joe is hypersensitive to insect bites.

Joe is home today. He feels as though someone were holding a blowtorch on him. His highly specialized machine will stand idle until the burning, maddening itch is relieved and he can get back on the job.

Dermesthetic Ointment*—*CUTTER

—will give triple-action itch relief while the underlying cause is being treated. Three anesthetic agents** offer fast, overlapping, and prolonged topical anesthesia. The base is greaseless and washable, no bandage is required, and normal work routines continue uninterrupted.

Your CUTTER supplier can furnish Dermesthetic Ointment in 1⅛ oz. tubes and 1 lb. jars.

Your request for clinical samples will be welcomed. Write CUTTER LABORATORIES, Berkeley 10, California. Dept. G-10.

Treat Filariasis Easily and Quickly with

HETRAZAN*

DIETHYLCARBAMAZINE

Lederle

The treatment of so large a portion of the population that is affected by a disease as filariasis requires a drug that is easy to administer. HETRAZAN Diethylcarbamazine *Lederle* is such a drug. It is provided in tablet form that may be given orally after meals.

The low toxicity of HETRAZAN and its high specificity for *Wuchereria bancrofti* and *Onchocerca volvulus*, its freedom from any toxic heavy metals, and its stability under varied heat and moisture conditions, make HETRAZAN Diethylcarbamazine *Lederle* the drug of choice in the treatment of filarial disease.

Scabies, until recently regarded as a disease of poverty or uncleanliness, today is known to be found in all *walks of life. This highly contagious* parasitic infestation not infrequently escapes detection, hence the possibility of its presence must always be kept foremost in mind when a red, punctate, inflamed pruritic eruption presents itself.

In the eradication of scabies Kwell Ointment, containing 0.5% gamma benzene hexachloride in a vanishing cream base, represents a significant advance in therapy. A single course of treatment consisting of one or two applications effects a cure in more than 90% of patients. Its action is prompt, positive, and is not burdened by secondary dermatitis or relapse.

Kwell Ointment is available at your wholesaler in 2 oz. and 1 lb. jars.

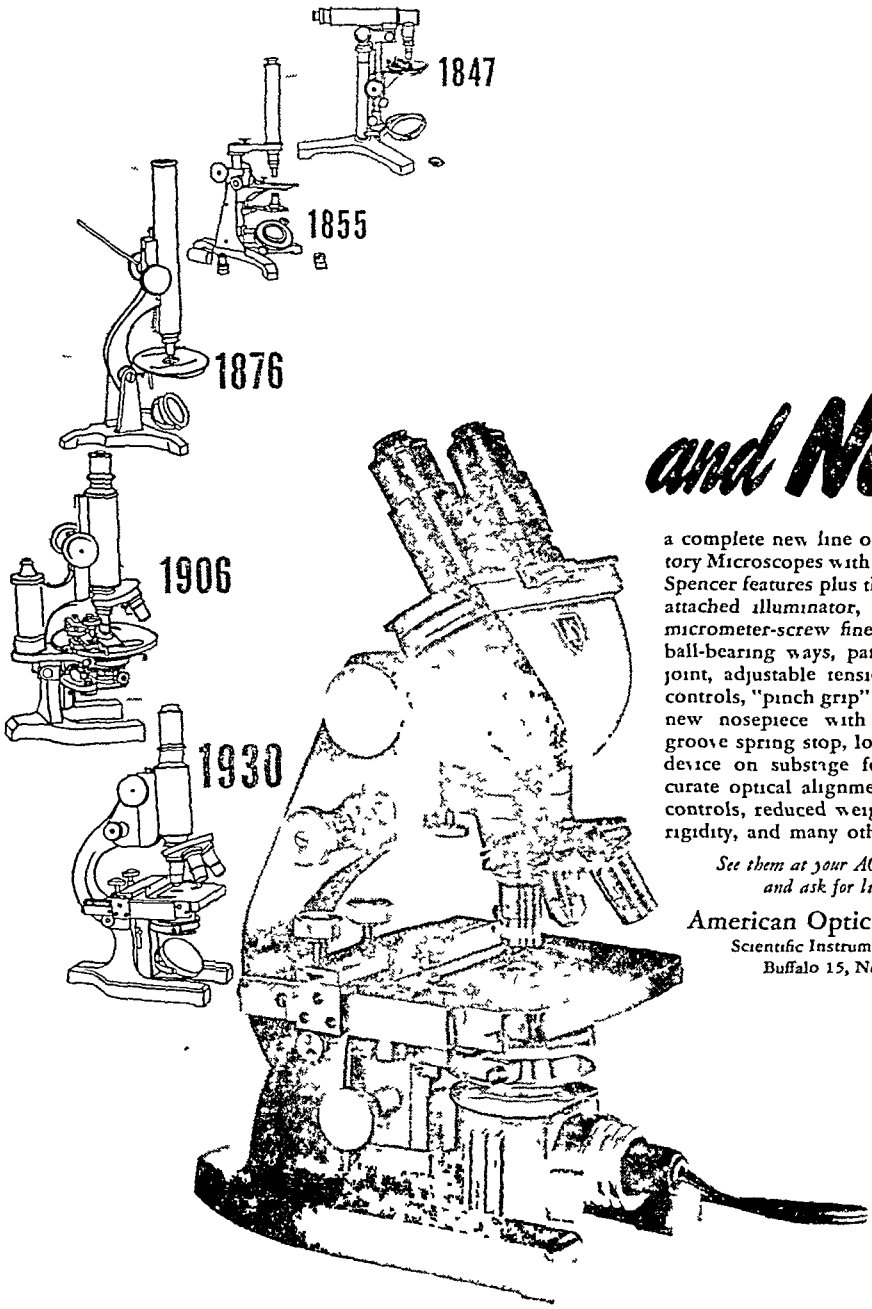
COMPLETE PROTECTION,



PLUS ECONOMY WITH

Dacro P-38

The smaller, more economical Dacro Cap . . . the P-38 affords the same dependable protection to milk purity as the larger Dacro P-45. It is still the only one-piece cap that actually seals the bottle air-tight and at the same time completely protects the pouring lip of the bottle. It's a handy re-seal, too. It may be snapped back on the bottle as often as needed, giving complete protection against contamination of the milk by refrigerator odors. For dependable protection under all circumstances and economy of application, Dacro P-38 is unsurpassed.

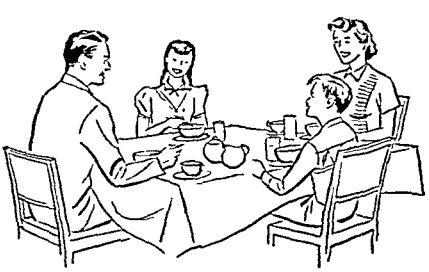
Controlled Study
CONFIRMS IMPORTANCE OF
Morning Meal

A study* recently concluded at the Departments of Physiology and Nutrition of the college of medicine at a distinguished university established that the value of an adequate breakfast, as recommended by nutrition authorities, is definitely reflected in maximum work output and mental acuity during the pre-noon hour.

It also demonstrated that the long continued omission of breakfast detrimentally affects maximum work output, simple and choice reaction time, and neuromuscular tremor.

Under adequately controlled conditions data were collected on the effects of four different breakfast habits on the maximum work output, mental acuity, and neuromuscular tremor of six young women ranging from 22 to 27 years in age. The breakfast habits investigated constituted habituation to an 800 calorie breakfast, effects of which were considered the critical standard, to no breakfast, to coffee only (1 cup of coffee, 1 ounce of cream, no sugar), and to a 400 calorie breakfast.

*Reprint of the study referred to will be sent on request.



From the data gathered the following conclusions were reached:

1. When "no breakfast" was the morning habit, maximum work output showed a significant *decrease*, while a notable *increase* resulted in simple and choice reaction time and in tremor magnitude.
2. Habituation to coffee only showed a similar *decrease* in maximum work output, with corresponding *increase* in reaction time and in tremor magnitude.
3. When habituation to the 400 calorie breakfast was accomplished after the "coffee only" period, a significant *increase* over the findings in the "coffee only" period in maximum work output resulted and both simple and choice reaction time as well as muscle tremor magnitude showed a noteworthy *decrease*.

The authors point out that no direct comparison could be made of the physiologic responses during the 400 calorie and 800 calorie breakfast periods, because the breakfast period of "coffee only" occurred between the 800 calorie and 400 calorie periods.

This controlled investigation now provides experimentally established support for the widely advanced admonition "Eat an Adequate Breakfast." For, though the authors do not draw this conclusion, it may well be reasoned inversely that maximum work output should be increased, and mental acuity improved, when faulty breakfast habits are replaced by the eating of an adequate morning meal.

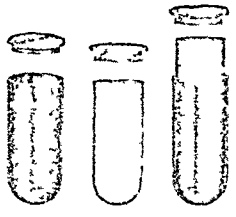
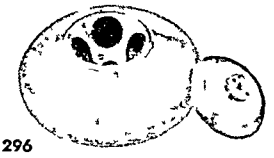
New Lusteroid Tubes

FOR HIGH SPEED CENTRIFUGING

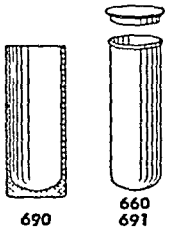


For Angle Heads on Multispeed Attachment

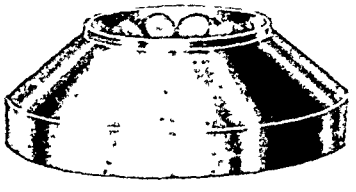


When used in conjunction with the Multispeed Attachment on the Reinforced Size 1, Type SB, Reinforced Size 2 and Model PR-1 Centrifuges, Head No. 295 swings six 10 ml. tubes at 18,000 r.p.m.; Head No. 296 swings four 25 ml. tubes at 18,000 r.p.m. At these speeds the problem of glassware breakage can be overcome by the use of Lusteroid (celluloid) tubes. As illustrated here, they are designed as inserts for aluminum or stainless steel shields which fit directly into the holes in the head. Plastic caps are available with tapered flanges which not only effectively seal the Lusteroid tubes but also prevent the tubes collapsing at the top under the high centrifugal force (25,000 x gravity).

HEAD NO. 295



295 Head, 6-place, Duralumin for No. 300 aluminum tubes and No. 658 Lusteroid tubes	$ 75.00
300 Tube, Aluminum, with flanged cover. Capacity 10 ml. No rubber cushion required. For No. 295 head only	7.50
658 Lusteroid Tube, 10 ml., for No. 300 tube. .	.10
671 Plastic Cap for No. 658 Lusteroid tube . .	.80
296 Head, 4-place, Duralumin, for No. 298 stainless steel tubes and No. 664 Lusteroid tubes	83.00
298 Tube, Stainless Steel and Cover. Capacity 25 ml., for No. 296 head only	8.00
664 Lusteroid Tube, 25 ml., for No. 298 tube.	.15
662 Plastic Cap for No. 664 Lusteroid tube . .	.85



HEAD NO. 296

For Large Capacity Angle Heads

Head No. 840 swings six 125 ml. tubes at speeds up to 5000 r.p.m. in the Size 1, Type SB, Size 2 and Model PR-1 Centrifuges. Head No. 845 swings eight 125 ml. tubes at speeds up to 4400 r.p.m. At these speeds Lusteroid tubes eliminate the problem of glassware breakage. When using the Lusteroid tubes, special rubber sleeve cushions No. 690 are also required. Plastic Caps No. 691 are available to seal the Lusteroid tubes and prevent collapsing at the top.

840 Head, 6-place	$185.00
845 Head, 8-place	200.00
660 Lusteroid Tube, 125 ml., *round bottom* for use in No. 690 cushion	.30

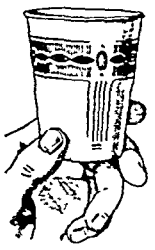
NOW SEALON HOOD PROTECTION Available to ALL DAIRIES

The Sealright Co., Inc., announces the introduction of a new one-head hooding machine which is especially designed for small dairy use. This smaller model of the famous Sealon Hood applying machine which is being used by so many of the country's larger dairies, now makes it possible for all dairies to protect their milk with Sealright's sterilized tamper-proof closure which completely seals the entire pouring surface.

Another New SEALRIGHT Sanitation Feature

The ordinary water spray in dairies is of low pressure variety and attempts to wash off excess milk on bottle top with excess water. The new Sealright, *high-pressure, low-water* volume Dri-Spray cleans and dries bottle tops without getting into a messy dairy operation.



Sealright

Announcing—

Salundek

A new antimycotic, proven to be effective in

TINEA CAPITIS

Control of this refractory fungus infection has been a distressing problem. Because of the inconvenience and possible hazards of X-ray treatment (1), research was stimulated for drugs for topical application.

In SALUNDEK Ointment, Wallace & Tiernan offers a practical solution to problems of dosage and penetration (2). Established antimycotics (undecylenic acid-zinc undecylenate) are combined with an effective penetrant in a proper base.

SALUNDEK Ointment is virtually non-irritating. With persistent application, the average case can be cured in a relatively short period.

Supplied in 1 ounce Tubes and 1 pound Jars. Available at all prescription pharmacies.

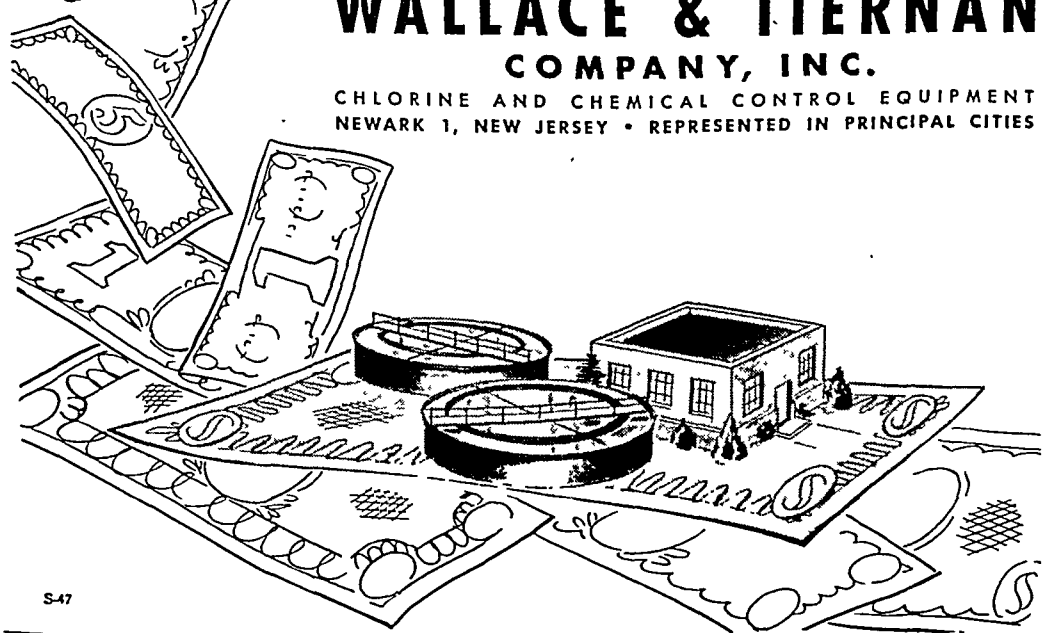
Sewage Treatment Dollars are bigger *with* Chlorination



Chlorination, fitted to your specific needs by W&T Engineers, gives you more treatment facilities per dollar than any other single treatment adjunct. It can be put to work at your plant for less than 1% of total plant cost in most cases. And for that 1%, chlorination by W&T is on the job ready to overcome such troubles as ODORS, PLANT OVERLOAD, FILTER PONDING, GREASE, and SLUDGE BULKING, wherever and whenever they develop.

Of course, to get these results, chlorination must be correctly applied. That's where W&T's 35 years of experience come in. Experience plus sturdy W&T Equipment—designed to take hard intermittent sewage plant use—adds up to one sure fact—that you will have the proper equipment, properly installed, to do a thorough job at low cost.

Call your nearest W&T Representative, now, for complete details on the full line of W&T equipment for effective sewage chlorination.

Variation in the Hospital Care of Premature Infants*

EDWARD R. SCHLESINGER, M.D., F.A.P.H.A., AND ELIZABETH PARKHURST, M.Sc., F.A.P.H.A.

Director, Bureau of Maternal and Child Health, and Senior Statistician, Office of Vital Statistics, State Department of Health, Albany, N. Y.

THE resolution on prematurity passed at the 1947 Annual Meeting and today's discussion at a joint meeting of the Health Officers and Maternal and Child Health Sections of the Association attest to the growing emphasis placed upon a public health approach to the problem of prematurity. We are leaving the hit or miss era in premature care and entering the stage of large-scale organized programs. If energy and funds are to be expended wisely in this field, critical appraisal must be made of the content of programs, existing and planned, and techniques must be developed to evaluate the results of such programs.

As a first step in this direction it is desirable to have a picture of the types of care given to premature infants in leading teaching hospitals, and to determine what effect, if any, variations in such care have upon the fate of the premature. Such knowledge is also helpful in planning additional or improved facilities for adequate care of premature infants in a given area according to accepted medical standards.

With these factors in mind a study was made of the care given to premature infants born during 1945 and 1946 in 6 teaching hospitals in New York State, 2 in New York City, and 4 elsewhere in the state. Data were obtained by statisticians directly from the hospital records of all infants weighing less than 2,500 gm. at birth covering such matters as birth weight, weight at time of transfer from one type of service to another, and on discharge from the hospital, and number of days' care given in incubators, in premature nurseries not in incubators, and in the regular new-born nursery. Lists of such infants supplied by each hospital were cross-checked with information on birth and death certificates available in the Office of Vital Statistics.

All the hospitals studied had special facilities for the care of premature infants including premature nurseries with modern incubators. The adequacy of

* Presented at a Joint Session of the Health Officers and Maternal and Child Health Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

TABLE 1

Per cent of Infants Weighing 1,750–2,499 Grams at Birth, and Surviving to Discharge, Receiving Care in Premature Nursery

Hospital	Per cent placed in premature nursery			Per cent of those placed in premature nursery receiving incubator care		
	1,750–1,999 grams	2,000–2,249 grams	2,250–2,499 grams	1,750–1,999 grams	2,000–2,249 grams	2,250–2,499 grams
Total	97	88	34	67	60	40
A	79	72	54	100	100	100
B	100	88	17	100	100	100
C	100	96	6	100	100	100
D	97	80	20	97	98	78
E	100	96	2	27	11	—
F	100	100	100	23	8	3

these facilities and the qualitative aspects of care rendered were not investigated. The data obtained can only provide a picture of actual practice in selected teaching institutions during a given period of time.

No significant variation was found in the 6 teaching hospitals in the type of care rendered to premature infants who weighed less than 1,500 gm. at birth. All infants in this birth weight group who survived the delivery room were placed in incubators in the premature nursery. In the birth weight group between 1,500 and 1,750 gm. only minor variations in care were noted. At the dividing line of 1,750 gm., deviations in the type of care became rather marked. As seen in Table 1, in 1 hospital only 79 per cent of the infants in the weight group, 1,750 to 2,000 gm. were placed in the premature nursery in contrast to the other study hospitals in which all, or nearly all, the infants were placed. Among the heavier prematures the differences in care were even sharper. In 1 hospital in New York City, all infants weighing up to 2,500 gm. received care in the premature nursery. In the other hospitals the percentage of infants placed in the premature nursery dropped off in the weight group 2,000 to 2,250 gm., and in 4 of the hospitals most of the infants in the weight group above 2,250 gm. were placed in the regular new-born nursery.

Further variation was discovered in the percentage of infants who received incubator care. In 3 of the 4 upstate study hospitals, all infants who entered the premature nursery were placed in incubators and remained there until discharge from the hospital, even though special heat and humidity controls were discontinued well before discharge. At the opposite extreme, in the hospital in New York City in which all infants less than 2,500 gm. were admitted to the premature nursery, incubator care was given to only 23 per cent of infants weighing between 1,750 and 2,000 gm., to 8 per cent in the next weight group, and to 3 per cent in the group just below 2,500 gm.

In the planning of facilities for care of premature infants it is important to have an idea of the average days of hospital care required for all premature infants, surviving or dying. In the study hospitals an average of 22 days of care is found for all premature infants (exclusive of those held for non-medical reasons) if a half day of care is arbitrarily assigned to infants dying during the first day of life. The range was 19 to 25 days. The greater part of the care was given in the premature nursery even in those hospitals in which the majority of the larger infants were placed directly in the regular nursery, since the hospital stay of the larger infants was comparatively short.

A similar analysis was made of the care rendered infants surviving to dis-

charge from the hospital as this gives a better picture of the actual care rendered. An average of 27 days of care was given to the surviving infants, with a range of 24 to 32 days in the various hospitals studied. The average number of days' care in incubators in the 2 teaching hospitals in New York City was very low since many infants were removed fairly promptly from the incubator to an unheated crib in the premature nursery.

These data were broken down further by weight, and the weight group 2,000 to 2,250 gm. is chosen to illustrate in detail the variations involved (Table 2). In the 4 upstate study hospitals about 12 per cent of the total care rendered premature infants was given in the regular new-born nursery. Of the 2 study hospitals in New York City, 1 gave no care to prematures in the regular nursery at any time, and the other gave only 1 per cent of care in the regular nursery.

Marked variation was also found in the proportion of care given in the incubator and in unheated cribs in the premature nursery. In the 2 study hospitals in New York City, 98 and 99 per cent of the total care to premature infants in the weight group 2,000–2,250 gm. was given in unheated cribs in the premature nursery as contrasted with the 3 other hospitals in which 73 to 97 per cent of care to the group was given in incubators.

The variation was also marked in the next lower weight group from 1,750 to 2,000 gm., although not so great. Extreme variations were found in the care of infants weighing between 2,250 and 2,500 gm.

Analyses of the average daily gain in weight and of the average weight at discharge at the various hospitals disclosed little information of interest. The average daily gain in weight was related in general to the length of stay of the infant in the hospital, being greater in infants who remained longer. A weight of about 2,500 gm. was apparently the criterion used in determining the time of discharge from the hospital, the range in the actual average weight at the time of discharge being 2,460 to 2,660 gm. No relationship was demonstrated between the birth weight of the infants and the weight at the time of discharge.

The neonatal case fatality rates (deaths under 1 month per 100 live births) by broad weight groups in each of the 6 study hospitals are shown in Table 3. Since mortality varies so markedly with the weight of the infant, the crude case fatality rate in any hospital is dependent to a large extent upon the distribution of the births in that hospital by birth weight. In order

* "Crude case fatality" includes infants whose birth weight was not stated but who were of premature gestation. The adjusted case fatality excludes them.

to obtain comparable total rates for each of the study hospitals which could then be compared with the rates for other hospitals, the rates for the 6 study hospitals were adjusted to the distribution of births by birth weight in all hospitals in the upstate area in 1945–1946. This adjustment was made by calculating the number of deaths per 100 births that would have occurred had the distribution of births by weight in each hospital been the same as that among births in all upstate hospitals.

The 2 study hospitals in New York City had definitely lower rates in each of the weight groups than did the 4 upstate hospitals combined and the difference between the adjusted total rates (21 per cent) is statistically significant. When the deaths under 1 day are excluded, the difference between the rates for the study hospitals in New York City and upstate is even greater, the rate for infants 1–29 days of age in New York City study hospitals being 36 per cent lower than in the study hospitals upstate. Hospital C upstate had rates lower than any of the 3 other upstate hospitals but, since there were only 130 premature births in this hospital in the 2 years of the study period, its rates are not significantly lower than those of the group as a whole.

The hospital with the lowest adjusted rate is hospital F in New York City. This hospital has paid particular attention to the problem of prematurity for many years. In reviewing the type of care given in this hospital, it will be recalled that all infants weighing less than 2,500 gm. at birth were admitted to the special premature nursery and kept there until discharge. In this hospital more infants are placed in incubators for a day or two and are then kept in the premature nursery when the incubator is no longer considered necessary. These infants, plus the infants placed directly in unheated cribs in the premature nursery, raise the proportion of care in unheated cribs far in excess of the other study hospitals. It is of interest that hospitals C and E, the hospitals with the next lowest adjusted rates, admitted the next highest percentages of infants up to 2,250 gm. to the premature nursery. In these hospitals, only 4 per cent of the total care to infants weighing 2,000 to 2,250 gm. at birth was given in the regular newborn nursery as compared with 12, 20, and 28 per cent in the 3 hospitals having higher rates.

It should be emphasized that no conclusion is being drawn that the differences in the types of care *per se* were

responsible for the lower neonatal case fatality rates. There are many other factors at work—above all, the quality of care rendered—which were not measured. However, in pointing out the association, it would seem that the methods employed by hospitals which save a greater proportion of infants could well serve as a model unless other methods are shown to be better in some or all respects.

For the upstate area, neonatal case fatality rates by birth weight are available for all hospitals, since infant deaths are routinely matched to their corresponding birth certificates, and birth weight is obtained on over 90 per cent of all certificates. Table 3 shows the rates for all hospital births, and also for those occurring in teaching and non-teaching hospitals. While the teaching hospitals are all fairly large (none had fewer than 900 births in 1945), tabulations have shown that except for slightly higher rates in hospitals having less than 100 births a year, there is little variation in the fatality rate according to size of hospital.

The rates in each of the 3 broad weight groups are practically the same as the corresponding rates in the upstate study hospitals, the total adjusted rate for the non-teaching group being slightly lower than for the teaching group which, in turn, is slightly lower than that of the upstate study group. None of these differences are statistically significant..

Exact comparison between the study hospitals, the teaching hospitals as a group, and others, is complicated by the fact that although birth weights are reported for over 90 per cent of all births, the group of births with weight not stated includes a considerable number of infants of premature gestation. Most of these, in view of the high correlation between gestation and birth weight, would weigh less than 2,500 gm. If these children are included in the total premature group, the mortality of the group is raised. In the non-teaching hospitals in Table 3, they formed 7.7 per cent of the total premature births, with a fatality rate of 46 per cent, and in the teaching group, 5.9 per cent, with a mortality rate of 25 per cent. If it were possible to distribute these births to the proper weight group, the total adjusted rate for the non-teaching hospitals would be increased more than that for the teaching group, probably eliminating the differences between them. In the study hospitals, birth weights were obtained from the hospital records for all prematures and this alone may account for the fact that the adjusted mortality for the upstate study hospitals appears slightly higher than for the upstate teaching hospitals as a group.

In comparing the case fatality among prematures in different hospitals, or in various areas, the inclusion of these infants with birth weight not stated is as important as the adjustment of the rates for birth weight.

For the evaluation of the results of a premature program, then, certain points must be kept in mind.

1. *In comparing case fatality rates,* mortality of all premature infants, regardless of the stated cause of death, must be included. The infant mortality from "premature birth" as given by statistics of infant deaths by cause is not an adequate measure of the mortality associated with premature birth. For a state, county, or city, this means the matching of infant deaths to birth certificates and obtaining accurate birth weights on all birth certificates. Birth weight has been included on the face of the Standard Certificate to be adopted in 1949. Effort must be made to obtain complete data on birth weight since the failure of some hospitals to record the birth weights of infants who die soon after birth reduces the comparability of mortality figures for these hospitals and the areas which they serve.

2. Deaths included should be those occurring in a stated age period, for example, under 1 month of age. Hospital data are likely to include all deaths occurring in the hospital, regardless of age at death, and to exclude occasional deaths at less than 1 month of age that occur after the infant has left the hospital.

3. The births should include all those occurring at a particular place during a stated period of time. Hospitals should not include infants born outside and moved to the hospital after birth. These infants have already survived the period of greatest hazard.

4. In order to be comparable, case fatality rates should be computed by birth weight groups, or the total rates adjusted for differences in the distribution of births by birth weight.

SUMMARY

1. Marked variation was found in 6 teaching hospitals in New York State in the average number of days' care given premature infants and in the type of care given those weighing 1,750 gm. or more at birth. Some hospitals placed a considerable proportion of the larger infants in the regular new-born nursery. Only 3 of the hospitals had crib facilities other than incubators in the premature nursery.

2. The 3 hospitals which made the greatest use of special facilities for premature infants had the lowest case fatality rates. There appeared to be no association between the average number of days' care and case fatality.

3. Evaluation of premature programs necessitates the development of adequate statistics on the case fatality of all premature infants, regardless of stated cause of death. Because of the marked variation of the fatality rate with birth weight, it is essential that a rate adjusted for birth weight be used in comparing case fatality rates.

Outbreak of Yellow Fever in Panama Controlled

Dr. Miguel Bustamante, Secretary General of the Pan American Sanitary Bureau, reports that no cases of yellow fever have occurred in Panama since December 31, 1948, indicating that the results of the work performed by the health authorities of Panama, with the aid of personnel and vaccine contributed through the Pan American Sanitary Bureau, by Brazil, Colombia, and the United States, were completely successful. Dr. Adhemar Paolielo, of the Pan American Sanitary Bureau, has reported from Panama that by April 15, 1949, 315,000 persons had been vaccinated against yellow fever and that most of the dwellings throughout the country had been sprayed with DDT. The teamwork among the four countries and the international health agency for the Americas was benefited by an increased budget for public health in Panama. The people of Panama provided all possible facilities and coöperation.

The Care of Premature Infants in New York City*

HELEN WALLACE, M.D., F.A.P.H.A., AND
LEONA BAUMGARTNER, M.D., F.A.P.H.A.

Chief, Maternity and Newborn Division; and Assistant Commissioner for Maternal and Child Health Services, City Department of Health, New York, N. Y.

THE problem of reducing the number of deaths associated with premature birth has become a matter of major concern to those interested in reducing infant mortality rates in this country. The basic problem is, of course, to increase our fundamental understanding of the causes of premature birth. But there is also the immediate problem of saving those viable infants who are born before term. Since experience has demonstrated that the lives of such babies can often be saved by proper care, an increasing number of public health officials, hospital administrators, and physicians have become interested in promoting community-wide programs for premature babies. Few reports of such activities are found in the literature and those which have appeared, have, with the exception of Chicago, dealt almost exclusively with state-wide programs.[1–5] A description of experience with the problem in another urban area would therefore seem pertinent.

Many groups in New York City have long been interested in the problems associated with prematurity. Some of the city's hospitals and medical schools have made important contributions to basic research in these problems. A city-wide committee, appointed by the Commissioner of Health, has developed desirable standards of care, kept mortality statistics, investigated hospital facilities, promoted better autopsies on the new-born. The war interrupted many of these activities, but with the EMIC program,* other activities in behalf of certain premature infants were undertaken. A study of these cases reveals some interesting material. During the war, the Department of Health also developed a hospital consultation service.

The materials herein presented attempt to answer only three of the questions usually asked by an administrator starting a so-called "premature program."

1. What is the current situation as to incidence of and mortality among prematures?
2. What are the weakest aspects of the care now given the prematurely born infant?
3. If financial assistance is to be given, what can one expect the costs to be?

MORTALITY AND MORBIDITY

Since 1939, the first year that birth weight was recorded on the birth certificate, from 7.1 to 8.3 per cent of all babies born alive have weighed less than 2,500 gm. Infant and neonatal mortality rates in New York City as else-

* Presented at a Joint Session of the Health Officers and Maternal and Child Health Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

* A study of EMIC and non-EMIC infants born in the war years is being made and will contain additional materials relating to the subject of infant care.

TABLE 1

Premature Births and Deaths under One Year of Age
(Known Birth Weight of Less than 2,500 Grams)
New York City — 1947

	Births		Deaths of Premature Infants	
Weight Group	*Number*	*Per cent of Premature Births*	*Number*	*Per cent of Premature Births*
Up to 999 grams	584	4.2	546	93.5
1,000–1,499 "	859	6.2	471	54.8
1,500–1,999 "	2,307	16.8	416	18.0
2,000–2,499 "	10,032	72.8	491	4.9
Total	13,782	100.0	1,924	14.0

where, have dropped steadily but the reduction in the neonatal rate has been slower. In 1947, the infant rate was 26.4, the neonatal 20.1.

MORTALITY AMONG PREMATURES

The mortality among live-born babies with a recorded birth weight of less than 2,500 gm. has fallen since 1945 from 17.1 to 14 per cent. Figures for 1947 * are shown in Table 1. The overall mortality was 14 per cent.

It is impossible to compare this figure with any other urban area, since apparently no other large city analyzes all its infant deaths in relation to birth weight. Most births (99.8 per cent) in New York City occur in hospitals, so it is of interest to compare these figures with those collected by Dunham[6] for the period 1940–1945 in 6 hospitals in large American cities, in which the per cent fatality ranged from 15 to 27.4. The figures for many reasons are not directly comparable, but they indicate that the mortality rates of prematurely born infants in New York City are certainly not excessive.

The extent to which prematurity looms as an important factor, however, is seen when one considers infant deaths in relation to birth weight. Thirty-eight per cent of all infant deaths in New York City today occur in infants with a recorded birth weight of less than 2,500 gm. The mortality rate in such infants is 13 times that of babies weighing more than 2,500 gm. "Prematurity" is listed as the chief cause of death in 38 per cent of all infant deaths, the cause of death being verified by an autopsy in 44 per cent of the cases. Potter and her associates[7] have indicated the need to evaluate carefully "prematurity," when it is listed as a cause of death on the death certificate and is not verified by an autopsy. Moreover, it is common knowledge that the autopsies usually performed on infants are so poorly done that one cannot rely too heavily on their results. Nevertheless, when all available facts are surveyed, it is quite clear that the deaths associated with premature births constitute the chief problem in infant mortality today.

WHAT CARE IS AVAILABLE

In planning a community program for prematurely born infants, among the first questions asked is "How good is the care now available?" Many assume that because of the existence of outstanding medical centers in large metropolitan areas, the care available to all infants is far above the usual standards. Our observations have not borne out this conclusion. For example,

* In 1947 there were 3,895 babies born in New York City whose birth weight was unknown. Length of gestation was known, and it was possible to allocate these babies by birth weight groups. As a result of this allocation, the corrected incidence of prematurity in 1947 was 8.6 per cent, and the corrected mortality per cent among prematurely born infants 16.7.

there are in New York City, 110 hospitals with maternity services. Of these, 20 could not meet the minimum standards set up under the EMIC program, and so could not be approved for payment when the plan was in operation. A survey (by the questionnaire method) of equipment provided in the 110 hospitals in 1946, showed that only 1 had an incubator and only 61 had a heated crib ready in the delivery room to receive the prematurely born infant. Moreover, no incubators at all were available in 19 maternity hospitals and 3 had no means (except hot water bottles or heat pads) of providing the additional heat needed by the premature. The preparation of formulae was such, in many hospitals, as to throw doubt on the safety of the product made.[8]

A team from the Department of Health, composed of obstetrician, pediatrician, epidemiologist, and public health nurse with special training in maternity and new-born care, has visited maternity hospitals regularly since 1944. They assist hospital personnel in analyzing weaknesses, and attempt to help hospitals improve their services. Surveys made by this team show that many hospitals use techniques which are outmoded, are wasteful of nursing time, or even encourage the spread of infection. Findings of these surveys and the progress made by providing competent consultant service in the nursing, pediatric, obstetric, and epidemiological fields have been reviewed elsewhere.[9]

Suffice it to point out that the problems found in hospitals lie in four areas:

1. Failure to carry out well established medical policies in a case suspected of having an infection, or the lack of consultations in complicated cases.
2. Lack of qualified supervision of nursing care.
3. Lack of physical equipment, such as incubators, and of facilities to cope with hemorrhage, shock, and asphyxia.
4. Failure to teach mothers about the care of themselves and their infants and to consider home conditions before discharging the baby.

It is the hospital with the small maternity service which not only gives a poor grade of care throughout its service, but is particularly unprepared to give modern care to prematurely born infants. But this situation is, perhaps, best revealed when one reviews findings in individual hospitals. Four typical cases have been selected. Of these, three are of the poorest type of hospital, for it is here that the chief problem lies.

Hospital "A," a small proprietary hospital, has designated a pediatrician in charge of the new-born nursery, but this designation is "on paper" because the pediatrician comes to the nursery only when called to see an individual baby in consultation with, and at the request of, the attending physician. He has no other responsibilities, nor can he assume any. As there are no definite policies indicating when he should be called, such requests are indeed rare. There are no established policies and procedures, no written standing orders to guide physician or nurse. Each physician orders for his own babies. The premature infants are fed with the routine house formulae prescribed for the full-term infants. On one visit to the nursery, in which the maximum capacity had been set at 20, 22 full-term and 6 premature infants were found packed in, with scarcely room for doctor or nurse to observe a baby. There had been no increase in the "nursing" staff to care for the additional 8 babies. There was no trained nursing supervisor for the nursery. Most of the nursing care was supplied by untrained staff members, practical nurses, attendants and aides who were not registered nurses, and who, it must be remembered, were working without supervision. There were, at the most, 2 so-called "nurses" and sometimes only 1, for this entire group of 22 full-term and 6 premature babies. Premature babies are fed with propped bot-

tles, and gavage tubes are passed by poorly trained personnel. The one incubator available in the nursery presumably has its temperature checked at intervals, but this information is never recorded so that no one knows what the previous temperature has been. All infants, both premature and full-term have their temperature taken "routinely" once a day, regardless of condition. Mothers are not taught how to care for the babies when they are ready to go home. No attention is paid to home conditions. Arrangements with the community nursing agency so that the premature infant would be protected in the home, if it were able to survive this type of hospital care, could have been made. Transfer of a premature infant to a hospital better able to care for it is effected only if the baby is about to die, the purpose apparently being to avoid having the death recorded as occurring in this hospital. Records on all babies, including prematures, are practically nonexistent. The record form for the infant has no space for progress notes, physical examinations, consultation notes, laboratory data. The only information available is the temperature and the weight, which are recorded every two days. No record is made of feeding, symptoms of illness, or behavior.

Hospital "B" is almost a replica of Hospital "A." On a visit to Hospital "B" a 3 pound premature infant, born 12 hours previously, was found in a private room. No physician had seen the baby since birth. A private duty nurse, an elderly woman who had just recently returned to nursing, was employed to care for the baby. Since she had not seen a premature baby in years, she was standing around the room not knowing what to do. This baby died during the visit of the Health Department's consultants to the hospital.

In Hospital "C," care of premature infants is equally substandard. Premature infants are cared for in the full-term nursery in the same manner as full-term babies. There is no trained nursing staff at any time during the day or night. The 1 untrained worker provided for the nursery also spends about 2 hours in the formula room preparing formulae, during which time the nursery is completely uncovered. Premature babies are fed with propped bottles, as are full-term babies. As a typical example of the kind of care given in such a hospital, for a 5 day period, the temperature of 1 small premature infant weighing 3 pounds 8 ounces at birth, was never taken. The infant was in an incubator, but the temperature of the incubator was never checked or recorded. The baby was not seen by a pediatrician until a week after birth, when its condition became critical. A review of the baby's record during the 13 days it survived, revealed no report of any physical examination at any time or any progress notes by any physician. Certainly a baby of this weight, which was in sufficiently good state to survive 13 days under these conditions, could probably have lived on, had adequate care been continuously available.

In contrast to these three illustrations of substandard care, Hospital "D" is an example of the type of care which should be available to all premature infants.

There is an excellent pediatric staff responsible for all procedures in the premature unit. There is, too, a well supervised house staff. Medical policies are based on scientific investigation, and the procedures are well carried out. There are daily rounds made by the attending pediatrician, as well as weekly teaching rounds. The quality of the staff is attested by the fact that even physicians of good standing prefer to give up the care of their patients to the trained pediatric staff available. Annual statistics of the premature unit are kept, and are used as a guide in an effort to improve care. These statistics, incidentally,

bear out the impression that excellent care is given to premature infants. A manual on the care of the premature infants has been developed as a guide for both physicians and nurses. The nursing staff is under the supervision of a nurse who has had considerable training and experience in the field of pediatric nursing. Although this hospital has been affected, as have all hospitals, by the current nursing shortage, it has, nevertheless, been possible by wise allocation of duties to provide sufficient nursing care through the use of auxiliary workers who are not nurses. Emphasis is placed on having *good* supervision and on special training for all those who work with the premature. The premature unit is self-contained, almost completely segregated from other services of the hospital. Considerable space has been allocated so that there is no overcrowding. There is sufficient utility, work, and storage space. Premature infants are held or supported when fed, and bottles are never "propped." When gavage tubes are used, they are introduced by experienced pediatricians and nurses or by auxilliary personnel under close supervision. Recording of the infant's reactions and feeding is done carefully and intelligent use made of the information so recorded. Mothers are taught how to care for their premature babies, so that they have a feeling of security and competence when they finally take them home. The hospital also uses another method to maintain a close relationship with the parents. Each evening, the resident physician in the premature unit has office hours, so that parents may confer with him in person or by telephone. There is, too, an excellent working relationship with the community nursing service; home conditions are investigated prior to the discharge of the baby, and the public health nurse actually helps with the care of the baby in the home. The hospital reports a smaller number of readmissions since this system has been in use.

COST OF CARE

It is well recognized that care of the premature baby is costly—careful nursing, oxygen, transfusions, etc., are items which add appreciably to the cost of care. Actual cost figures indicate that $18 per hospital day (as of April, 1948) is not exorbitant, that cost varies widely from hospital to hospital, and that costs are mounting rapidly. Nevertheless, the administrator needs to know what doctors and hospitals can be expected to request in caring for prematurely born infants. An analysis has been made of the cost of caring for 378 infants under the EMIC program in New York City in 1943, 1944, and 1945. In the group were 353 infants weighing less than 2,500 gm. and 25 who weighed more but were declared "premature" by the physicians who cared for them and for whom special service was requested, given, and paid for. These 25 are included in the cost figures because it is believed that care for such babies (i.e., debilitated or "immature" infants slightly over 2,500 gm.) will usually be asked for.

CONDITIONS OF PAYMENT

In order to interpret the data, it is necessary to know the pertinent facts relating to payments allowed. Hospital care was paid for on a cost basis and varied from hospital to hospital. During the period covered by this report, the average cost was approximately $8 a day, with a ceiling set at $8.25 so that more than this could not be paid. Hospital care of a new-born infant was paid by EMIC only after the mother was discharged. Since the average length of hospital stay of the EMIC maternity patient in New York City was 9.8 days, an additional maximum of 9.8 days' cost should be added in order to calculate payments made for hospital care for EMIC premature infants. This fact

TABLE 2

Payments Made for Care of Premature Infants by EMIC Program, New York City, 1943–1945

Type of Service Paid for	All Prematures		Prematures Who Survived		Prematures Who Died	
	Amount of Money	Per cent of Total	Amount of Money	Per cent of Total	Amount of Money	Per cent of Total
Hospital *	$64,011.34	80.0	$61,276.64	80.1	$2,734.70	74.3
Attending Physician †	5,084.00	6.3	4,902.00	6.4	182.00	4.9
Consultant	2,572.00	3.2	2,376.00	3.1	196.00	5.3

Ambulance and Drugs	45.00	0.1	33.40	0.1	11.60	0.6
Totals	$80,168.02	100.0	$76,489.87	100.0	$3,678.15	100.0
Average cost per case	$212.09		$217.30		$141.47	

* Includes cost of all hospital care, exclusive of the first 10 days of life except for those infants who were transferred from one hospital to another.

† Includes cost of all attending physician care, exclusive of the first 14 days of life.

does not apply to the EMIC premature infants who were transferred from one hospital to another, or for those who died.

Payment to the attending physician also requires interpretation. Under the regulations of the EMIC program in existence during the period covered by this report, the physician who delivered the mother was not paid additionally for the care of the new-born infant during the first 2 weeks of life. Therefore, in calculating true costs of paying for medical care, for the premature infant only, allowance would probably have to be made for additional payment to cover this early period. EMIC fees paid to the attending physician were $3 for a home visit; $2 for an office or hospital visit; for long-standing care the fee was $24 for a 3 week period, and $6 for each additional week. After December 15, 1944, diplomates of the American Board of Pediatrics were paid fees 50 per cent higher than those quoted.

Since prematurity was considered a condition requiring special care, pediatric consultation was strongly urged for all premature infants. Payment to qualified consultants was made from birth on at the following rates: $15 for the first home visit and $10 for each visit thereafter; $10 for the first office or hospital visit and $5 for each visit thereafter. Practically all consultation care for this group of EMIC premature infants was given in the hospital. Consultants were considered "qualified" if they were certified by specialty boards or had training and experience equal to that required for entrance to Board examinations.

It should be emphasized that the amount of service required—medical, hospital, nursing, consultation, and the miscellaneous types—was decided by the physician rendering care to the individual patient. Presumably, therefore, the amount of care given to this group of EMIC patients was determined only by the medical condition and needs of the individual patient.

OVERALL COSTS

A total of $80,168.02 was expended for all types of care rendered to this group of 378 infants, or an average cost of $212.09 per infant. A more detailed analysis of the cost is presented in Table 2.

Table 2 shows that the great bulk of funds (80 per cent) was spent for hospital care, with approximately 10 per cent more for medical care, and 8 per

TABLE 3

Amount Paid for Supplementary Services Given Premature Infants, EMIC Program, New York City, 1945–1946

Service	No. of Cases in Which Care Was Paid	Per cent Infants Receiving Care	Aver. Paid per Case	Range of Pay
Private Nurse	16	4.2	$16.99	0–$1,705.00
Visiting Nurse	42	11.0	0.39	0– 15.00
Oxygen	18	5.0	3.07	0– 420.00
Blood and Plasma	20	5.0	1.02	0– 50.00
Breast Milk	9	2.0	0.89	0– 82.62
Ambulance	3	1.0	10.00	None
Special Drugs	4	1.0	15.00	None

cent for nursing care. The average cost per case of the group who survived was $217.30 as compared with $141.47 for the group who died. These figures are probably high, since this particular series of infants contains relatively few premature infants who died within the first few hours of life.

Hospital care was paid for 368 of this series of 378 infants at an average of $169.34 per case. There was a range from "no payment" to $900. Payment to the attending physician was made for 165 of this series. Of the remaining 213 infants, 204 were ward cases in which no individual physician was paid. There was a range from "no payment" to $228 per case with an average of $30.81 paid per "non-ward" case.

Payment for consultant service so that the general practitioner could benefit from the greater experience of the qualified pediatrician was encouraged. In many instances individual attending physicians were called and this service offered. It was used in only 17 per cent (65 out of 378) of the 378 cases, but as pointed out below, a considerable number of these infants were ward patients who were already under the care of pediatricians so that special consultation was not indicated. Payments for consulting pediatricians for the entire group averaged $6.80 per case with a range from "no payment" to $195. For those babies for whom service was provided, the average amount paid was $39.57.

These figures, however, do not give a complete picture of the amount of pediatric care that the EMIC premature received. Of the 26 premature infants who died, 14 were cared for by a pediatrician and 12 were ward patients. Therefore, presumably, all infants who died were seen by a pediatrician. Of the 352 premature infants who survived, 78 were seen by a pediatrician and 168 were ward patients. This then makes a total of 246 or 67 per cent of those prematurely born infants surviving who were seen by a pediatrician.

The average and range paid for other supplementary services are seen in Table 3. It is interesting that only a small number of cases received such supplementary services.

Visiting nurse agencies did not charge for routine visits made as part of the community-wide program of visiting newly born infants. Of the 42 cases paid for, an average of only 2.4 visits were made per case. The one special medication paid for by EMIC for this group was penicillin.

The cost of these services, exclusive of special nurses which became more important under wartime conditions, was thus very small. It seems doubtful if these special services added enough to the income of the hospitals to compensate for the work entailed in securing approval for payment. Nevertheless, the fact that payment could be made did much to improve relationships with physicians, families, and hospital administrators and in some instances was important for infants' welfare.

TABLE 4

Average Length of Hospital Stay of EMIC Premature Infants by Birth Weight Groups, New York City, 1943–1945

Weight Group	Totals			Infants Who Survived			Infants Who Died		
	Number of Infants	Number of Hospital Days	Average Length of Hospital Stay	Number of Infants	Number of Hospital Days *	Average Length of Hospital Stay	Number of Infants	Number of Hospital Days †	Average Length of Hospital Stay
Under 1,000 grams	5	180.6	36.1	2	175.6	87.8	3	5	1.6
1,000–1,499 "	42	1,995.0	47.5	29	1,677.2	57.8	13	317.8	24.4
1,500–1,999 "	134	5,267.0	39.3	129	5,166.2	40.0	5	100.8	20.2
2,000–2,500 "	172	4,457.0	25.9	167	4,341.6	26.0	5	115.4	23.1
Over 2,500 "	25	610 0	24.0	25	610.0	24.0	..	..	..
Totals	378	12,509.6	33.1	352	11,970.6	34.0	26	539.0	20.7

* The above figures were estimated by adding 9.8 days to the number of days paid for in the cases of infants who survived.

† Estimates of length of stay of infants who died were based on the number of days paid for and age at death.

LENGTH OF STAY IN THE HOSPITAL

The length of time that the baby will have to stay in the hospital is an important factor in determining the cost of his care. Under the EMIC program, the medical status of the infant was supposedly the only factor determining the amount of hospital care needed, since the financial question did not arise. The average length of hospital stay of the 352 prematurely born infants in this study who survived was 34.0 days and of the 26 infants who died 20.7 days.[10] It must be remembered that many prematures who died within the first few hours were not included in the calculation of length of stay. Further data on the length of stay by birth weight group are presented in Table 4.

It is seen that in the series of infants who survived, the group weighing less than 1,000 gm. remained in the hospital approximately 3 months; the group weighing 1,000–1,499 gm. approximately 2 months; the group weighing 1,500–1,999 gm., 1½ months; and the group 2,000–2,500 gm., approximately 3½ weeks. The group who died represents such a small sample, that no valid conclusions may be drawn regarding length of stay.

AMOUNT OF TRANSPORTATION

In planning a community program for the care of prematurely born infants, the administrator must have some estimate of the expected amount of transportation of infants from one hospital to another or from the home to a hospital. In this EMIC series, 24 per cent of the premature infants who died and 6 per cent of those who survived, or 7 per cent of the total group, were known definitely to have been transported.

In another study of premature infants who died in New York City in 1946, it was found that 19 per cent of the prematures in this other series were transferred.

SUMMARY

1. Some of the problems facing those interested in reducing the number of infant deaths associated with premature birth are presented, using factual materials collected in New York City during the past three years. The emphasis is placed on those which are of interest to the administrator who may wish to plan a special program of care for the prematurely born infant.

2. In 1947, 14 per cent of the babies with a recorded birth weight of less than 2,500 gm. died in the first year of life. Deaths of these babies accounted for 38 per cent of all infant deaths, and the mortality rate in the prematurely born group was 13 times that of babies weighing more than 2,500 gm.

3. Surveys of all hospitals showed a wide variation in the kind of care given. There was great need for improvement, particularly in the hospital with a small maternity service.

4. Studies of payments made under the EMIC plan for prematurely born infants show an average cost of $217.30 a case for those who survived, and $141.47 for those who died.

5. The average length of hospital stay of the premature who survived in this series was approximately 30 days. All of those who died and two-thirds of those who survived were seen by a pediatrician.

Passano Award to Dr. Avery

Oswald T. Avery, M.D., Emeritus Member of the Rockefeller Institute for Medical Research, received the 1949 Passano Foundation Award of $5,000 at the annual award dinner in Atlantic City on June 8, during the annual meeting of the American Medical Association. The award goes to Dr. Avery for his extensive investigations of the pneumococci, their classification, analysis and immunological relationships. Dr. Avery was one of the five A.P.H.A. Lasker Award winners in 1947 "for studies on the antigenic constitution of bacteria." He is a member of the Association.

The Passano Foundation, established by Williams & Wilkins Company, medical publishers, Baltimore, to aid advancement of medical research, has previously made other awards to E. J. Cohn, Ph.D., Harvard University, for his work on fractionation of blood; Ernest Goodpasture, M.D., Vanderbilt University, for virus culture by chick embryo method; Selman Waksman, Ph.D., of Rutgers University, for discovery of streptomycin; and last year a joint award to Helen B. Taussig, M.D., and Alfred Blalock, M.D., both of Johns Hopkins University Medical School, for "the blue baby operation."

The Child Health Institute in Rochester, Minnesota*

BENJAMIN SPOCK, M.D.

Department of Neurology and Psychiatry, Mayo Clinic, and Psychiatrist, Rochester Child Health Institute, Rochester, Minn.

THE Rochester Child Health Institute, which from its start in 1944 until its incorporation this year was called the Rochester Child Health Project, has as its concern the physical and mental health of all the children of Rochester, Minn., a city of 33,000. It does not function as a self-contained institution, nor are its basic aims very original. Many of the services to which its staff contributes are not new to Rochester. There were well baby and well child clinics before; there was a nursery school before. Most of the services to which it contributes are actually under other auspices: the Rochester and Olmsted County Health Unit, the well child conferences of the Mayo Clinic, the section on obstetrics and gynecology of the Mayo Clinic, and the public and parochial schools. Even its staff is largely borrowed from other institutions: pediatricians and psychiatrists from the staff of the Mayo Clinic, fellows in pediatrics and psychiatry from the Mayo Foundation, and public health nurses from the Rochester and Olmsted County Health Unit and the University of Minnesota.

What is it then? Basically it is a focal point which draws together agencies, individuals, and points of view in the field of child health, and then tries to bring them to bear on the children through available activities. When staff and facilities are not available or not sufficient elsewhere the Institute itself may supply them. That is why it has 3 psychologists, 1 full-time and 1 half-time pediatrician, a nutritionist, and a nursery school supervisor who are its very own, not loaned by anyone else. It also has some secretaries and statistical workers. It has some small offices of its own. In one respect its situation is unusual. There are only two private practitioners of medicine in Rochester who are not connected with the Mayo Clinic, and neither of them is a pediatrician. Therefore the Institute has the field of preventive pediatrics and psychiatry almost entirely to itself.

Dr. Henry Helmholz, for many years head of the section on pediatrics at the Mayo Clinic, conceived the idea, won the medical backing of the clinic, and the financial backing of the Mayo Association, and persuaded Dr. C. A. Aldrich who had pioneered in the fields of mental hygiene and child development within the field of pediatrics, to become director. The Mayo Association provided the entire financial support until this year, when the Institute was incorporated in order to appeal for the additional funds necessary if it is to fulfil its broad aims.

Prenatal care is carried out in two clinics: those of the sections on obstetrics and gynecology of the Mayo Clinic and the Rochester and Olmsted

* Presented at the Round Table on The Family as the Unit of Health, in connection with the Twenty-fifth Annual Conference of the Milbank Memorial Fund, November 17 and 18, 1948. The proceedings of the Round Table will be published in a single volume by the Milbank Memorial Fund.

County Health Unit in the city hall. The latter is staffed by public health nurses, the Institute nutritionist, and fellows in obstetrics from the Mayo Foundation, supervised by a Mayo Clinic staff consultant. Prenatal classes for expectant parents have been tried a few times in the past with only moderate success. We want to try again when we have more staff and more wisdom. A few obvious cases of emotional disturbance in pregnancy are referred to psychiatry in the Institute, but we do not yet have the staff which we want for the routine psychiatric evaluation of all prenatal patients.

Practically all Rochester babies are born, at the rate of about 600 a year, in St. Marys Hospital, which is staffed medically by the Mayo Clinic and Foundation. A member of the section on pediatrics of the Mayo Clinic who is also on the staff of the Institute is in charge of the new-born nurseries, and he and a fellow in pediatrics make rounds to see all the mothers daily. This is the first contact between the mother and the Institute staff proper. A family history is taken. The Institute philosophy, with its emphasis on respect for the child's own developmental pattern, self-regulation of diet and schedule, and value of breast feeding, is gotten across through casual conversation on rounds, through the fellow's longer individual talks with each mother, and through printed leaflets, 3 of which are given during the 8 day lying-in period.

Within a couple of days of going home a public health nurse makes a home visit.

The babies return to the well baby clinics at monthly intervals during the 1st year, five times the 2nd year, and twice the 3rd, 4th, and 5th years. There are two clinics, the largest run by the Rochester and Olmsted County Health Unit at the city hall six half days a week and staffed by an Institute pediatrician, Mayo Foundation fellows in pediatrics, and the public health nurses. A smaller clinic for private patients, which meets five afternoons a week at St. Marys Hospital, is similarly staffed except that the pediatrician is a member of the section on pediatrics of the Mayo Clinic.

Again, the emphasis in the doctor-parent conference and in the leaflets, which are different for each age period, is on what to expect at each developmental stage and how to adjust to it. Dr. Leona Baumgartner of the New York City Health Department, who visited the Institute recently, said jokingly that in the usual well baby clinic you see the doctor talking and the mother nodding, but that in Rochester the mother is talking and the doctor nodding.

Medical examinations are given all children before they enter kindergarten or the 1st grade, and also during the 5th grade, 9th grade, and 12th grade. In addition, children in other grades are examined if they have had previous lesions or if examination is requested by the teacher, parent, or public health nurse. The examinations are unusually careful as school examinations go, being scheduled at the rate of one every twenty minutes. The parent is invited to be present (for children under high school age), the public health nurse is present, and the teacher is available. The referrals are pediatric, dental, and psychiatric.

The public health nurses are distributed predominantly on a geographic basis so that a family has the same familiar nurse whether at the well baby clinic, a school health examination, or a sick call.

There is a wise nutritionist on the staff of the Institute who consults in the prenatal clinics and the well baby clinics, works with the teachers in the schools and takes referrals generally from the public health nurses.

At present there are three nursery schools in Rochester for 115 three year and four year olds, organized by a citizens' committee and supervised by an expert from the Institute. Tuition is paid in full or part by parents but some scholarships are provided by service clubs. There is a total of five sessions a day, with two paid teachers for each session. Two of the nursery schools are located in public school buildings through the courtesy of the school board, but there is no other official connection with the public school system. There is also a nursery school run by the Catholic parochial school which the Institute nursery school supervisor advises.

The psychiatric staff of the Institute consists of a half-time pediatrician with psychiatric training, a part-time psychoanalytic psychiatrist who supervises the direct psychotherapy of children, and three Mayo Foundation fellows in pediatrics and psychiatry. There are referrals of early problems from the well baby clinics, from the schools, from the public health nurses, from the psychologists of the Institute, and from parents directly. Once a week there is a psychiatric case conference in one of the schools, at which a problem child is discussed from the points of view of teacher, public health nurse, and pediatrician. The emphasis is as much on community management as on psychotherapy, as much on prophylaxis as on treatment.

Mental Health Act funds now are available to the Rochester and Olmsted County Health Unit for a small counseling clinic for adults and children. It will have a psychiatrist-administrator and a well trained psychiatric social worker to start with. When it is actually set up, the psychiatric staff of the Institute will function as part of its staff in respect to cases which require any appreciable length or intensity of psychotherapy. The simpler problems of the early childhood years, which mainly require advice to parents, will be handled in the pediatric setting in the well baby clinics, whenever possible by the fellows in pediatrics, under psychiatric supervision.

The psychologic staff consists of three experienced people who at present are concentrating on a fairly thorough evaluation of all the children as they reach the age of 2½ years. There are three aspects to this evaluation: a Stanford-Binet test, a determination of the child's present adjustment in such areas as feeding, toilet training, sleeping, discipline and sociability, and a discussion with the parent. In the latter, the child is not compared with other children but is interpreted in terms of his individual needs.

Plans are being made to repeat the psychologic evaluation as each child reaches the age of 5 years. These cross-sectional estimations at 2½ and 5 years are only a more thorough addition to the developmental and adjustment data secured at every pediatric visit. They have already shown, however, the inaccuracies and the omissions in the routine questioning of the less experienced fellows in pediatrics. They have shown also, even in a community where psychiatric and psychologic advice is freely available, that for every parent who has spontaneously sought help for a problem such as toilet training resistance, there are several who have struggled along without mentioning it.

Another plan in the psychologic field is to ask each school teacher to evaluate each of her pupils each year on an adjustment questionnaire which we have prepared. This will help us to keep track of the children's development in the school years when the pediatric contacts are infrequent and will, incidentally, help the teachers form better estimates of their pupils.

The Rochester Child Health Institute

has so far worked successfully in a number of directions. The pediatric supervision of all the children of the city is good especially in the preschool years. The percentage of kept appointments for routine check-up is impressive. The philosophy of respect for the child's individual developmental pattern really seems to get across to the majority of parents. I think it shows, for instance, in the striking infrequency of feeding problems. As a newcomer in Rochester, one is impressed by the relaxed, friendly, accepting attitude of most mothers in the clinics. The value of healthy emotional development is recognized by staff, fellows in training, and parents. The desire for nursery school facilities keeps increasing. Some of the individual psychologic problems in children are being helped and the staff is learning how to detect them, how to prevent them, and how to treat them. All these gains will be applicable elsewhere. But we all feel that we have made only a beginning.

We are aware of the lack of continuity in guidance between pediatric visits and between psychiatric visits. The public health nurses in their present numbers are too few to follow up all the problems between visits. The small departments of city and county welfare have their hands full with the more severe social problems.

There is much fundamental research to be done concerning normal development, both physical and emotional, and the interrelationships between the two. What part do inborn temperament, parental attitudes, and place in the family play in developmental patterns? Can inappropriate parental attitudes be changed before the child is born by methods that have a wide application? What part is to be played in the future by pediatrician, public health nurse, psychologist, social worker, nursery school and grade school teacher, and psychiatrist in guiding children's all-round development? We all know how individual children have been helped, but we certainly have not yet worked out a blueprint for using all the professional resources of the community for all the children. How far can pediatricians be helpful in preventive psychiatry? Should a corps of guidance psychologists or psychiatric social workers be trained to take up where the pediatrician leaves off? Can the values of nursery schools for children and their parents be spread thinner over more of the community?

We want to experiment with guidance nurseries for the flexible use of a large number of children and parents with no registration and no preconceived duration of attendance. We want to experiment with itinerant nursery school teachers who will move from neighborhood to neighborhood, showing children how to have fun with each other, and showing parents how to get along with their children near home or in it. We have got to experiment for decades with different approaches to parent education, going back at least far enough to reach the future parents when they are in high school. We have hardly begun to make contact with all the other organizations, from the city council and the Young Womens Christian Association to the Kiwanians and the real estate board, who do not think of themselves as child care agencies but are influencing children nonetheless.

I would like a chance to make another progress report on the problem in 25 years.

Relation of Nutrition to Infection in Children*

JUNIUS M. RAWLINGS, M.D.

Children's Health Center, Hurley Hospital, Flint, Mich.

THE topic "The Relation of Nutrition to Infection in Children" [1,2] is one that has long intrigued the minds of many interested observers. The present study consists of clinical observations, only, on a group of 315 children followed for periods of 3 to 32 months in an outpatient department.

Before presenting the specific data it may be helpful to recall some of the facts of body metabolism as revealed by recent studies in other fields. Rudolf Schoenheimer,[3] by the use of radioactive carbon, hydrogen, etc., was able to trace the pathway of food substances in the body. By this means, a new tool for metabolic research has been provided, and as a result, a dynamic concept of the interchange of foodstuffs is now accepted, in which even the constituents of bone[4] are shown to be constantly used and renewed.

Remarkable strides are being made in the study of all phases of the body's metabolism by the use of this tool of radioactive isotopes. One of the most revealing of recent investigations is the demonstration that the metabolism of body fat[5] uses virtually the same enzyme systems known to be used in the splitting of sugars. This discovery is a most important contribution to the understanding of the *common pathway*[6,7] used by the body when obtaining energy from basic foodstuffs.[8] Though proteins[9-12] may be used as an energy source their more important use is to replace worn out and destroyed protoplasm. Fats[13] serve in several capacities, being used chiefly by the nervous system and for protective and insulative purposes as well as an excellent source of energy. Additionally, minerals[14,15] and vitamins[16-18] are equally essential for life.

METHOD

Children, ages 2 to 17, were sent, chiefly by city and, in part, by county health department nurses, from schools of a metropolitan city area following screening by teachers, to the outpatient department of a philanthropic health organization—The Mott Foundation Children's Health Center—where diagnosis was made. Children chosen had to show either some form of chronic infection or a faulty nutritive status or both. Of the 315 cases seen, all but 11, or 96.5 per cent, had some form of chronic infection present. The children came from medically indigent families only.

Observation was made in each case over periods that varied from 3 to 32 months. At least 2, and usually 4 to 5, visits were made per patient to the outpatient department. Such visits were most frequently at 1 to 2 month intervals. Careful history and physical medical examinations were performed on each child with laboratory work as indicated to establish the diagnosis. The

* Presented before the American School Health Association and the Food and Nutrition Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 10, 1948.

assistance of a dental department, an ophthalmologist and an otolaryngologist was also available. Medical advice and treatment was given according to the nature of the illness found, but in all cases some form of supplemental therapy was administered consisting of vitamins ABCD, with iron and liver additionally, where it was considered essential. Sulfadiazine or penicillin was administered also when more acute illnesses supervened.

FINDINGS

An exceptionally poor nutritional status or an infection of greater than usual severity occurred 63 times or in 20 per cent of all cases. Multiple conditions were seen to be the rule, with 85.8 per cent of all patients presenting 2–5 different diagnoses at the same time on the first visit.

Diseased tonsils led the list and were found in 72 per cent of all cases. Involvement of the upper anterior cervical lymph nodes was second and was found in 67.3 per cent of all cases.

A faulty nutritive status, as determined by clinical observation alone, made up 125 out of 315 cases, or accounted for 39.5 per cent of cases seen. Such nutritional defects included marked thinness, definitely poor muscle tone, rough skin, dry hair, increased scleral vascular injection, undue prominence of papillae of tongue, redness or magenta discoloration of tongue, fissures at angles of mouth, gingivitis not associated with dental causes, extreme nervousness for which no other cause could be assigned, and evident pellagra, rickets, or other fully developed faulty nutritional status. However, it should be remarked that fully developed cases of clinical malnutrition and avitaminosis were but seldom encountered.

In children, the commonest statement made in complaint by the mothers concerning the child when questioned was that the appetite was poor. The next most common complaint was the observation that the child was nervous.

The one procedure that was somewhat routine, when indicated, was tonsillectomy and adenoidectomy. However, the T and A's purposefully were delayed to see what remedial effect supplemental therapy would have. The total of 315 cases were divided into 3 groups. Group I of 227 cases, or 75.27 per cent, had no T and A's performed. Group II of 32 cases, or 10.47 per cent, had T and A's at the *end* of their period of observation, while Group III of 56 cases, or 14.26 per cent, had T and A's *during* their period of observation. In Group I, consisting of 227 children, 139 were considered to need T and A's when first seen. This was based on evidence of real infection or marked hyperplasia of the tonsils or adenoids or both. All 227 in Group I, however, were started immediately on supplemental therapy, along with such other immediate medical treatments as were deemed essential. At the end of their period of observation, 3 to 32 months, all but 6 of the 139 had improved to a point where no T and A's were needed.

There were in all a total of 1,058 diagnoses rendered. Of these, 696, or 65.7 per cent, pertained to infections, and 177 diagnoses, or 16.7 per cent, to some defect in the nutritional status, irrespective of defective teeth and its possible nutritional connections. Thus, infections and nutritional defects together accounted for 82.4 per cent of diagnoses recorded. In all, 59 different diagnostic headings were used. Infections accounted for 31 of these headings and nutritional disturbances for 10 of them, or together for a total of 41 out of 59 diagnostic headings.

The sexes are about evenly distributed, 156 being boys and 159 girls. The greatest number of individuals seen were in the age range 5 to 12 years inclusive, while ages 5 and 6 years accounted for the greatest numbers, be-

ing 46 and 44 persons respectively.

Weight gains were quite variable. Losses were present in 3 per cent; no gains in 6 per cent with ½ to 5 pound gain in 53 per cent, while 5½ or more pounds gain was made by 38 per cent of all children seen. High gains of 15–32 pounds were made by 5.7 per cent. Thus gains of some kind were present in 91 per cent of all children seen.

COMMENT

It is felt that the frequency of serious past illnesses [19,20] is important and here it is found that pertussis [21–23] heads the list, being practically 3 times as frequent as the next most frequent past illness, which is pneumonia. Pertussis is a far more serious illness than it is often given credit for. It is the cause, not only of the highest mortality found today among the communicable diseases of children, but it is also a precursor of chronic illness of such frequency as to merit close attention. Rheumatic fever, otitis media, scarlet fever, and measles as past illnesses occurred in a decreasing order of frequency, with only a scattering for all other causes.

SUMMARY OF RESULTS

Supplementation, consisting of vitamins A–D, B-Complex and C with, in some cases, iron and liver additionally, was administered to 315 children for periods of 3 to 32 months. Three hundred and four out of the total of 315 cases had some form of chronic infection present. In this group of 304 cases, improvement was noted in all the types of infections found, as well as an improvement in the nutritional status, excepting only 11 cases, 10 being not improved, and one being worse. Thus, only 3.6 per cent of the total seen were not better following 3 months or more of the supplemental therapy. Or, in other words, of 304 cases, 293 or 96.4 per cent were better.

In addition to a lessening of the infection and the poor nutritional status, improvement was frequently seen in several other ways; namely, (1) a better appetite, (2) an increased growth, (3) an improvement in school work, and (4) a better attitude and behavior pattern.

An analysis of the results showed that 72.0 per cent of all cases fitted into the top three brackets of results—well, very much better, and much better on a 3 month minimum time period, while 85 per cent fitted into the same top three brackets on a 10 month minimum period of treatment and observation. This then shows 13 per cent better results for the longer minimum observation and treatment period than for the shorter.

Groups I and II together consist of those cases having supplementation *only* during the period of observation. Here, the longer 10 month minimum period for supplementation increased the good results in the top three brackets from a total of 69.7 per cent to a total of 82.9 per cent, or an increase of 13.2 per cent for the longer minimum period.

Group III, which is supplementation *plus* T & A performed during the period of observation, showed an overall better result than for supplementation alone. This held respectively for the 3 and 10 month periods of observation showing 82.2 per cent and 90.0 per cent of good results in the top three brackets respectively for the 3 and 10 month minimum periods. Thus, for Group III the 10 month minimum period showed approximately 7.8 per cent more good results in the top three brackets than did the 3 month minimum period.

CONCLUSION

Supplementation alone, for a 10 month minimum period of observation and treatment, showed 82.9 per cent of children well, very much improved, or much improved. Where T & A's seemed indicated and were done additionally to supplementation, 90 per cent of all children so cared for fitted into the same category of well, very much improved, and much improved. While the numbers of children seen are not many, the trend, it is felt, is quite significant. It is felt, therefore, that when dietary supplementation is administered to all cases of chronic infection, for a proper length of time, there is produced, in a large majority of such children, a very real and significant reduction not only in the infections and poor nutritional status found, but also in other retardations so commonly present.

Large U. S. Fund For "Backward" Areas in Prospect

According to a press notice in the *New York Times* of May 15, it is believed that from 10 to 15 per cent of the funds sought for the world task of aiding backward areas, in accordance with point 4 of President Truman's State of the Union message last January, recommending aid to such areas, would be spent in each of the fields of health, education, and agriculture. The remainder of the fund would presumably go to development, through technical advice and otherwise, of such projects as roads and transport, flood control, power development, mineral and oil exploration, fisheries, and industrial development.

Officials of the Department of State pointed out that, although the needs of the under-developed parts of the world are tremendous, the possibilities for spending funds are not. Because the program deals with technical assistance chiefly it must be keyed to available trained man power.

The State Department has come to an increasing realization that the real limit to progress and expense is the number of scientists and technicians available to do the job.

Of the total of $105,000,000 expected, $30,000,000 would be asked in a new appropriation by the United States Congress and $20,000,000 in appropriations. It has already been asked to contribute to certain United Nations agencies along similar lines and to the Institute for Inter American Affairs; $18,000,000 would be expected from Britain, Canada, France, and, perhaps other countries; $37,000,000 would come in local currencies of the countries being aided. While the new program would take over and correlate similar assistance which is already being carried out through the Institute of Inter American Affairs, it would not be involved with the technical assistance program of the Economic Coöperation Administration. The latter agency is seeking $16,000,000 for technical assistance in the Marshall Plan countries but for a different purpose because a more immediate contribution to European Recovery is being sought.

Influence of Protein Nutrition on Experimental Infection*

Physiological Aspects

JACK METCOFF, M.D.

Assistant in Pediatrics, Harvard Medical School, Boston, Mass.

THE study here reported suggests that several differing forms of infection response in the experimental animal may remain adequate in the presence of severe protein deficiency. The extensive investigations reported from Cannon's Laboratory[1-9] favored a contrary infection-diet hypothesis—namely, that cellular defensive response such as antibody elaboration would be inadequate or defective in the protein deficient animal. This hypothesis is a natural outgrowth of the work of numerous groups of investigators. Schoenheimer, *et al.*[10] showed that the body proteins composing various tissues were constantly undergoing a degradation and resynthesis—were, in fact, in a state of dynamic equilibrium. Modification of physical chemical techniques, particularly the Tiselius modification of the electrophoresis of protein containing solutions,[11] resulted in more specific description of human plasma components. Among these was listed a globulin which moved more slowly than the two other distinct components he named in the electrophoretic field, hence was called gamma globulin. This substance has been isolated in Cohn's laboratory,[12] and constitutes about 10 per cent of the total plasma protein.[13] Enders demonstrated that a great many of the antibodies to certain infectious processes were to be found greatly, if not exclusively, concentrated in this fraction.[14] Kabat, however, pointed out that all antibodies were not gamma globulin, nor was all gamma globulin antibody.[15] White and others demonstrated that gamma globulin was apparently formed within lymphoid tissue and could be released into the systemic circulation by appropriate stimulation.[16] Since all cells are composed of protein containing protoplasm, Cannon's hypothesis that protein deficiency would seriously imperil antibody response has seemed eminently reasonable. The assumption of causal relationship between hunger, famine, and infection gained impetus from epidemiologic studies in Europe during the war of 1914–1918. The increased mortality—from tuberculosis particularly—was ascribed to nutritional deficiencies resulting from deprivation of proteins and fats.[17] This hypothesis has been, and remains, more conspicuous by reiteration than by demonstration.[18]

An adequate experimental approach is difficult to achieve since disease induced in the experimental animal may differ from that in man. In general, laboratory studies pertaining to response to infection associated with protein deficiency have measured phagocytic indices, humoral antibody titers produced by a nonpathogenic antigen, a lethal endpoint produced by a virulent, viable pathogen, or simply pathologic tissue changes. Concomitant studies of varia-

* Presented at a Joint Session of the Food and Nutrition and Laboratory Sections of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 11, 1948.

tions in specific physiologic responses to diet and infection have been rather limited. The response of an organism to infection under any imposed condition is characterized by many adaptive phenomena. It, therefore, seemed desirable to test the implications of protein deficiency and infection further by simultaneous observation of several physiologic adaptations to controlled dietary deficiency and specific infection.

The albino rat seemed an appropriate experimental animal since its diet could be well evaluated, and sufficient base line data pertaining to growth and various other physiologic variables were readily available. Two diseases of economic import were studied: a paratyphoid variant and tuberculosis. The rat is relatively susceptible to the former and resistant to the latter. Successful antibody elaboration following infection with *Salmonella typhimurium* is an important factor determining survival of the rat. Minimal susceptibility or pathologic change subsequent to tuberculous infection would be expected in the rat. In view of the hypothesis in question, severe, controlled protein deficiency in the rat should alter both these expectations.

METHODS

After several extensive preliminary experiments, young growing male Sherman-strain rats were standardized on a control basal diet for 7–14 days. Approximately half were then fed protein deficient diets for an appropriate interval prior to infection. The animals were then divided into experimental groups and inoculated as follows:

	Diet	*Infected*	*Non-infected*		*Total*
Salmonella	18% casein well nourished	20	10		30
	2% casein deficient	18	12		30
			HK †	*Diet Control*	
Tbc.*	18% casein well nourished	19	6	6	31
	8% casein deficient	20	6	7	33
					124

* Four weeks after infection half of the surviving tuberculous rats in all groups were acutely reduced to a 2% diet protein level.
† Heat killed bacilli injected.

At intervals before, and for 42–58 days after, infection, growth rate, food consumption, and several blood and tissue studies were observed. Details pertaining to these methods are reported elsewhere.[19, 20]

RESULTS

The results of the *Salmonella* experiment can be briefly summarized.

Progressive weight loss approaching 20–25 per cent of starting body weight attended protein deficiency. Rats on the adequate protein diet appeared to eat rather more than did deficient animals. However, when adjusted to calories consumed per 100 gm. of rat per 24 hours, consumption in both groups was similar. Infection did not alter *ad lib.* intake.

Commonly used clinical laboratory procedures such as total serum protein and hemoglobin concentrations, total leucocyte and differential counts were applied. The results were not remarkable. Serum protein concentration and total leucocyte counts were somewhat diminished in the protein deficient rats.

By simultaneous determination of blood and plasma volumes with a dye technique,[21] it was possible to estimate changes in circulating proteins and hemoglobin. Such determinations indicated that diet protein deficiency resulted in a 30–50 per cent decrease in unit circulating proteins and a 40–50+ per cent decrease in unit circulating hemoglobin. Infection, *per se*, exerted little influence upon the quantity of circulating protein; but did result in marked diminution of circulating hemoglobin in both diet groups. This latter observation seems compatible with the so-called "hypoferremia of infection."[22]

The cellular composition of a section of femoral bone marrow from each animal was observed for indications of the influence of diet or infection upon hematopoiesis. Reduction of these tabulations to the simplest comparison of white cell-forming *vs.* red cell-forming series (myeloid-erythroid ratio) revealed that protein deficiency was associated with a tendency toward a relative increase of immature myeloid forms—an interesting observation in view of the lower total peripheral leucocyte counts in this group, suggesting a possible lack of a WBC maturing factor. In general, infection seemed to induce minimal change in the bone marrow.

Blood cultures failed to reveal a significant difference in the incidence of bacteremia in the two diet groups. Nor was a mortality difference observed. Humoral antibody titers in response to either the actual infection or a "recall" dose of specific antigen, indicated that deficient animals attained titers equivalent to those of the well nourished groups. The anamnestic response of deficient rats, in fact, was relatively better than that of the well nourished rats. This observation seems quite interesting when considered in reference to the concomitantly determined electrophoretic patterns of the plasmas of these rats. Protein deficiency was characterized by depletion of the albumin and gamma globulin fractions. Despite circulating gamma globulin depletion, the deficient rats had adequate humoral antibody elaboration. Moreover, despite a marked change in titer following secondary antigenic stimulation, there was no change in gamma globulin. These observations reaffirm those previously made that all antibody is not gamma globulin and vice versa.[15]

As another means of examining the hypothesis in question, studies similar to the foregoing were carried out on rats infected with human strain *Mycobacterium tuberculosis,* since tuberculosis is commonly said to be associated with malnutrition. The results of these experiments also may be very briefly summarized.

Growth and food consumption patterns were similar to those previously ascribed to protein deficiency.[19, 23] Tuberculous infection did not alter this pattern.

Histopathological review of various tissues indicated that the typical granulomatous lesions attained maximal development within four weeks after infection. Recognizable organisms had greatly diminished in number within another four weeks. No apparent difference of structure, incidence, or persistence of the specific lesion was noted in the different diet groups. No deaths from tuberculosis occurred during the two month observation period.

Changes in leucocyte and differential counts, hemoglobin and plasma protein concentrations, circulating protein and hemoglobin were essentially similar to those described in the protein deficiency and *Salmonella experiments*[19, 23] and represented a response to diet rather than infection. Electrophoretic analyses revealed no specific circulating plasma protein component changes characteristic of tuberculous infection.

Detailed data pertaining to these studies are available.[19, 20]

COMMENT

In commenting upon results which seem contrary to prevailing social, empirical, and emotional bias, several important qualifications must be stressed.

An appropriate experimental procedure involving the single variable of protein deficiency has not yet been reported. Rigid conclusions cannot be drawn from a biologic study involving isolated changing physiologic responses rather than a specific unequivocal statistical endpoint. Moreover, clinical inference derived from observations on non-indigenous disease in a selectively malnourished rat must be attended by considerable reservation. These studies, however, do suggest that the concept of protein deficiency causing inadequate response to infection would appear to be an over-simplification of a many faceted phenomenon.

SUMMARY

Under the conditions of these studies, protein deficiency did not appear to alter the susceptibility, resistance, course, or physiopathologic responses to either *Salmonella* or tuberculosis infections in the young growing rat.

Laboratory Tests in the Diagnosis of Brucellosis*

NORMAN B. McCULLOUGH, PH.D., M.D.

S. A. Surgeon, U. S. Public Health Service, Assistant Clinical Professor of Medicine, Department of Medicine, University of Chicago, Chicago, Ill.

BRUCELLOSIS is a disease which may present an extremely diversified clinical picture. It may vary from a brief illness lasting only a few days to a prolonged chronic disease of many years' duration. In the acute stage, the symptoms are similar to those of many other infectious diseases, and the patient is usually ill enough to leave no doubt that he has a serious infectious disease. In chronic brucellosis, on the other hand, the symptoms are often multiple, vague, and difficult to evaluate. There are usually no physical signs, and the patient may not appear clinically ill. There are no pathognomonic symptoms or signs, and often the physician has only the patient's subjective complaints, which may closely simulate those of the psychoneuroses. In such a variable and poorly defined illness, a clear-cut clinical diagnosis is seldom possible. Under these circumstances, the physician must rely heavily upon laboratory examinations to substantiate or to render unlikely a diagnosis of brucellosis.

As with all laboratory procedures, a critical evaluation and understanding of the tests used in brucellosis are essential if they are to be a diagnostic aid rather than a pitfall. Diagnostic enthusiasm, coupled with uncritical reliance upon laboratory data has led not only to many wrong diagnoses, but also to defective clinical concepts of the disease.

The main laboratory procedures of use in brucellosis are: culture of the organism from the blood or other tissues, the agglutination test, the opsonocytophagic test, and the skin test.

CULTURE OF THE ORGANISM

The only positive proof of the diagnosis of brucellosis is isolation of the causative organism. Until recent years media and techniques for primary isolation of Brucella have not been adequate. Currently, the most widely used culture medium is Bacto-Tryptose broth fortified with vitamin B_1. We have found that Trypticase Soy broth † more nearly meets the growth requirements of many strains of Brucella. It is now used routinely in our laboratory. One per cent sodium citrate is added to the broth. Five ml. of the patient's blood is added aseptically to 75 ml. of medium and incubated at 37° C. in a closed jar. Ten per cent of the atmosphere is replaced by carbon dioxide which is essential for the initial growth of most strains of *Brucella abortus*. An occasional strain grows best in a slightly reduced oxygen tension. Certain strains of Brucella do not develop sufficiently in broth cultures to give gross evidence of their presence; they may grow feebly for a time and then die out. For this reason, frequent subculture to solid medium (Trypticase Soy agar) is neces-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

† Baltimore Biological Laboratory, Inc.

sary for isolation of such strains. Subculture also provides earlier identification of the organism. Routinely subcultures are made on the 4th day and on alternate days thereafter for a period of one month.

The most important single point in the isolation of the organism is frequent repetition of attempts. Daily cultures of venous blood for 7 to 10 days should represent the minimum effort in seriously suspected cases. Culture techniques are adequate to recover the organism when septicemia is present. The difficulty, however, arises in chronic brucellosis where septicemia is often absent or certainly not constant. Here, the culture of other tissues is of value. Occasionally the organism may be obtained by the culture of arterial blood following the injection of adrenalin; 0.5 to 1.0 ml. is given subcutaneously and an arterial puncture is performed 20 minutes later. In our laboratory, Brucella has been recovered from cultures of sternal marrow and lymph nodes when repeated venous blood cultures were negative. In all cases when other methods fail, biopsy of a lymph node is indicated. Unfortunately, a suitable hyperplastic lymph node is not always present. The culture of spinal fluid and surgical specimens may at times be worth while. Animal inoculation may be used in the case of tissues and specimens obtained with difficulty and when cultures cannot be repeated, but present culture methods are at least as reliable as animal inoculation.

By the diligent use of the described methods early in the disease, one should be able to recover the organism from most patients with brucellosis. We have yet to see a patient in the first 6 months of illness, in whom we seriously suspected brucellosis, from whom the organism was not recovered.

THE AGGLUTINATION TEST

The agglutination test is probably the most widely used diagnostic procedure in brucellosis. Seldom is such a commonly used laboratory method subject to so much controversy and misinterpretation. Aside from the biological variations due to the organism and to the host, the discrepancies which arise in performing this test are enormous. Sera of known cases of brucellosis when submitted to recognized laboratories yield highly variable reports. Recently we submitted 21 sera to 5 different laboratories.[1] Eighteen of these were called negative by one or more laboratories. Of these 18, 16 were elsewhere called positive in titers of 1/200 or higher, and 12 were called positive in titers of 1/320 or higher—titers which are frequently considered as substantiating a clinical diagnosis. Tests on the same sera in our laboratory against a number of "standardized" commercial antigens yielded as variable results. It is apparent that in everyday practice the reported titer of a serum depends as much upon the laboratory where the test is performed and upon the antigen used as upon the patient's disease. There is great need for standardization of antigens and technique.

Cross-agglutination with other organisms must be considered. It has long been known that there is an antigenic cross with *Pasteurella tularensis*. There is also a significant relationship between the organism of Asiatic cholera and Brucella.[2] An H antigen of *Vibrio comma* is shared by Brucella.[3] The majority of individuals receiving the standard immunization against cholera develop significant titers against Brucella. These may persist for 2 or more years.[4]

An occasional case of culturally proved brucellosis may fail to show agglutinins. Such cases have been reported by reliable workers, but this occurrence is rare. Unfortunately, some enthusiasts have stretched this concept to the point

that they consider the absence of agglutinins the rule rather than the exception.

On the other hand, a high titer is not necessarily indicative of active disease. We have had under observation for 4 years an Italian-born 50 year old man who claims he has never been ill in his life. He works at hard manual labor daily. Yet this man without a symptom or history of any illness consistently runs an agglutination titer of 1/5,000. There are numerous instances recorded of healthy individuals with tests positive in dilutions of 1/1,000 or more. This, too, is the exception.

There is, then, no "diagnostic" agglutination titer in brucellosis. In general, a titer of 1/320 or higher, in the presence of symptoms, is presumptive evidence of the disease. A fluctuating titer which correlates with the presence and remission of symptoms may suggest active infection.

A rising agglutination titer during the course of an undiagnosed febrile illness is of some significance. Here again, other mechanisms may be operative. An anamnestic response may confuse the interpretation. We have observed this phenomenon in a patient with experimental malaria. Prior to the attack the agglutination test was completely negative, but there was slight opsonic activity of the blood. A few days after the onset of malaria the agglutination test became positive in a titer of 1/80, returning to negative again a few weeks after recovery. It is conceivable that higher titers might occur.

After vaccine therapy, of course, it is impossible to interpret the results of an agglutination test. A single injection of vaccine may render the test meaningless for months.

THE OPSONOCYTOPHAGIC TEST[5]

Compared to the agglutination test the technique of the opsonocytophagic test is more involved and must be more precise. Slight variations in technique or slight dissociation of the test organism render the results worthless and misleading. To insure dependability, control blood from known positive and negative individuals must be included each time the test is run. The test must be performed shortly after the blood is drawn. This alone renders it impracticable for the practitioner who does not have ready access to a specialized laboratory. Probably few laboratories perform this test in a reliable manner. Granted that results were dependable, the added information obtained from this test is not great. Opsonic activity probably does in some degree reflect bodily response to the disease. However, during active infection, the test results fluctuate so greatly as to be of little prognostic value. The test may be helpful when a patient has a low agglutinin titer and a markedly positive opsonocytophagic reaction. This suggests an immune state rather than active infection. It is also of some use when negative, as corroboration of a negative agglutination test and a negative skin test, thereby rendering the diagnosis of brucellosis quite unlikely.

THE SKIN TEST

Of the many skin test materials advocated, brucellergin[5] is the most generally accepted and the best standardized. The skin test is of very limited diagnostic value. It should be interpreted analogously to the tuberculin test. A positive test merely means that the individual has at some time been in contact with Brucella sufficiently to become sensitized. A minimum requirement for a positive test should be induration and edema of 0.5 cm. in diameter present at the end of 48 hours. However, the test is commonly misread, with transient erythema being considered as a positive test.

A small percentage of patients with brucellosis do not develop allergy. Also,

early in the course of the disease the skin test will be negative. There is little correlation between the intensity of response and the likelihood of active infection. A negative test may be of some value in rendering the diagnosis of brucellosis unlikely, and in our practice this is its chief use. Cholera vaccination does not produce a positive skin test,[2] nor does tularemia. The skin test may then be helpful in differentiating Brucella agglutinins from those engendered by these conditions.

It should be remembered that antigenic material is injected in performing this test. A small proportion of individuals will develop agglutinins and opsonins after a skin test, even though the test be negative. Hence, all other antibody tests should be completed before a skin test is done.

Finally, in the absence of positive cultures, every bit of information about the patient must be considered in establishing a diagnosis. The opportunity for exposure must be considered. A careful evaluation of the symptoms and clinical course, the physical findings, and the results of all laboratory data are necessary. The results of laboratory tests considered apart from the patient are meaningless. The diagnosis of brucellosis should not be made enthusiastically but critically.

14 American Republics in WHO

On April 27, 1949, the delegate of Uruguay to the United Nations, Professor Enrique Rodriguez Fabregat, deposited at Lake Success Uruguay's ratification of the Constitution of the World Health Organization. Fourteen countries of the western hemisphere have now ratified: Argentina, Brazil, Costa Rica, Chile, the Dominican Republic, Ecuador, El Salvador, Haiti, Honduras, Mexico, Paraguay, United States, Uruguay, and Venezuela.

This means that the World Health Organization and the Pan American Sanitary Organization are now authorized to conclude a permanent agreement for the latter to become WHO's regional office for the western hemisphere. Since March 1, 1949, the Pan American Sanitary Bureau has been the acting regional office under a temporary working arrangement signed by Dr. Brock Chisholm and Dr. Fred L. Soper of WHO and Bureau respectively.

Chronic Brucellosis*

The Unsatisfactory Status of Current Diagnostic Methods

HAROLD J. HARRIS, M.D., F.A.C.P.

Westport, Essex County, N. Y., and New York, N. Y.

THERE is much misunderstanding and misuse of the available laboratory methods in chronic brucellosis, with low grade or no fever. The need is great for a laboratory procedure comparable in accuracy to the blood complement-fixation reaction for syphilis. Until such a test procedure can be developed it is necessary to interpret the available reactions with greater accuracy and greater caution than is commonly employed.

SKIN TESTING

Although it has been recognized by almost every worker in this specialized field that skin testing with any effective *Brucella* antigen may stimulate agglutinins and opsonins, often in marked degree and for prolonged periods of time, there persists a tendency on the part of some clinicians to follow the easiest course, i.e., early and hasty performance of the intradermal test, prior to performance of the blood agglutination and opsonocytophagic tests. These clinicians then look to consultants, laboratory technicians, and bacteriologists for diagnostic help and are disappointed when told that they have committed the unpardonable sin—that of beclouding or destroying all other laboratory evidence (except that which may be obtained from culture).

Harm is done by the occasional report in the literature[1] which tends to absolve the skin testing antigen of agglutinin- and opsonin-stimulating properties. The concept has only recently gained acceptance that agglutinins even in low titer may have diagnostic significance when considered along with other laboratory and clinical data. In fact a tentative diagnosis may be largely influenced by such a combination as specific agglutinins in a titer of 1:40, a positive intradermal reaction (subsequently performed), and some degree of specific phagocytosis, in the presence of a clinical picture suggesting brucellosis. Since agglutinins in any titer are usually lacking in chronic *Brucella* infections, it is nothing short of carelessness to risk destroying the small chance that exists of obtaining diagnostic information through agglutinin (and opsonin) testing, on non-skin tested patients.

Routine skin testing of apparently well persons is to be condemned. It serves no very useful purpose for it does not distinguish the actively infected *Brucella* sensitized patient from the subclinical or inactive infection with persisting skin allergy. It does tend to induce artificial agglutinin and opsonin response which can cause diagnostic confusion if those persons later become ill with symptoms suggesting brucellosis. Furthermore, skin tests, even with the most reliable antigen (i.e., killed whole organisms) may fail to detect past or present *Brucella* infection; not rarely are skin tests negative in the

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-sixth Annual Meeting in Boston, Mass., November 9, 1948.

presence of positive culture and high agglutinin titers.

The skin test is valuable only in conjunction with the battery of other specific tests, clinical history, and the nonspecific laboratory procedures such as complete blood count, sedimentation rate, and the like. It is a serious error to overstress the value of any of the single tests for none is definitive, except culture—and that only when positive.

Another error is the use of a nucleoprotein such as brucellergin for the intracutaneous test. It is unreliable. In 1938 Angle and his coworkers,[2] in the course of skin testing large groups in an attempt to determine the incidence of *Brucella* infection, especially in school children, carried out skin tests on 163 adults who had been using raw milk from an infected herd. Brucellergin and killed whole *Brucella* organisms were used simultaneously, in opposite arms; 89 patients (54.6 per cent) reacted to killed *Brucella* organisms, but of these only 44 patients (26.9 per cent) reacted to brucellergin. No conclusions were drawn from these findings other than that brucellergin is less likely to cause skin necrosis. In recent years a series of similar observations were carried out among patients referred to the writer because of clinical or laboratory evidence or both, of brucellosis. Among 48 patients tested with brucellergin and heat-killed *Brucella abortus* oganisms simultaneously, 35 patients (72.9 per cent) reacted to the whole organism and of these only 17 (35.4 per cent) reacted to brucellergin. Among those reacting to heat-killed *abortus* organisms but not to brucellergin was one whose blood agglutination reaction was positive in a titer of 1:1,280 and whose blood culture yielded *Brucella suis*.

Individuals skin-tested with brucellergin, even though with negative results, may become sensitized, thereby giving false-positive reactions to subsequent skin tests with other antigens. When skin tests carried out simultaneously with brucellergin and other antigens agree it may be due to contamination of syringes used for brucellergin skin testing with killed whole *Brucella* organisms.

It is true that brucellergin has a lesser tendency than killed whole organisms to produce skin necrosis but its lesser sensitivity as an index of *Brucella* allergy is too high a price to pay for this supposed advantage.

Weak reactions to intradermal antigens must be considered positive. They differ in significance from strongly positive reactions only in the degree of *Brucella* sensitivity indicated in that patient. Even this difference is not uniform, for some patients have little or no skin allergy but marked allergy in other tissues (e.g., negative skin test, positive culture, or agglutination reaction or both, and marked local, focal or systemic reaction to therapeutic doses of *Brucella* antigens).

Bacterial antigen complexes (BAC-Hoffman[3]) made from each of the three separate species of *Brucella* are under investigation as skin testing agents. They may not prove to be species-specific but they do give information as to species-allergy and therefore offer a useful guide to treatment by means of the same antigen. They may be used to supplement the information obtained from intradermal use of killed whole organisms.

BLOOD AGGLUTINATION REACTION

Brucella agglutinins are seldom present, even in low titer, in the chronic illness. Therefore it is essential that the technique be meticulous and that the exact titer be reported to the physician. It is generally agreed that titers of 1:80 or above are of definite significance and that lower titers *may* be significant. The preponderance of evidence indicates that a monovalent anti-

gen is adequate. The antigen should be a standardized and effective one, such as the alcohol treated suspension of smooth *Brucella abortus* employed by the Division of Laboratories and Research of the New York State Department of Health.[4] It is common, even now, for widely discrepant readings to be reported by two or three different laboratories on parts of the same blood specimen.

The microscopic blood agglutination technique, in titers of 1:40 and 1:80 only, is a useful screening method,[5] but must be supplemented by the macroscopic tube technique for greater accuracy and to determine exact titer.

The possibility of a prozone reaction[6-8] must not be forgotten. Sera must be examined in high as well as in low dilutions.

An explanation of the failure of agglutinins to appear or their tendency to disappear after once being present in patients in whom the disease process continues was offered by Griffitts.[8] Sera from patients known to be infected had the property of "blocking" agglutination of *Brucella* organisms suspended in a saline medium, but some of them agglutinated heavy suspensions of *Brucella* organisms suspended in a serum or albumin solution.

Other warnings regarding interpretation of the agglutination reaction are necessary. Cross-agglutination may occur in the presence of other infections due to *Pasteurella tularensis, Salmonella typhosa, Bacillus flexneri* and *Vibrio cholera*,[9,10] and perhaps in certain Rickettsial and viral infections. Cholera prophylactic vaccine as well as cholera infection may produce *Brucella* agglutinins (and opsonins). That fever of any origin[11,12] may produce specific *Brucella* agglutinins in uninfected persons has not been substantiated.

Agglutinins in apparently well persons may not be ignored. They may presage active, severe infection,[6] or subclinical infection[13] which later may become severe.

OPSONOCYTOPHAGIC REACTION

It is erroneous to consider this test result qualitatively. It should not be considered "positive" or "negative" for it simply expresses the degree of resistance possessed by the patient's phagocytes. With this concept there will result less confusion, for any degree of phagocytosis (from none to marked) may occur in the presence of *Brucella* infection. It is true, however, that phagocytosis of appreciable degree probably does not occur in the absence of *Brucella* infection, past or present. In that sense only, may a moderate to high reading be considered "positive." Never may any reading properly be called "negative."

The commonest errors in the actual performance of the test procedures are: (1) use of blood more than 3 hours old, (2) use of too high a concentration of citrate, (3) use of rough (dissociated) organisms or contaminated cultures, (4) use of non-virulent *Brucella* organisms, (5) use of any but the most meticulously careful technique in each step of the procedure. Inaccurate results from poor technique have led many workers to discard the test as unreliable. It is of great value as part of the battery of tests although of limited value in itself.

Most workers have found the *abortus* species alone a satisfactory test organism no matter what the infecting species, although some carry out the test with at least two species of *Brucella* separately. This adds to the expense and effort and has the disadvantage of exposing laboratory personnel needlessly to the more virulent *melitensis* or *suis* species.

Foshay and LeBlanc[14] devised a most helpful nomogram for the computation of a numerical phagocytic index. With the aid of Dr. DeWitt Smith a still

simpler and equally accurate method has been devised. The number of cells showing marked phagocytosis is multiplied by 4, those showing moderate phagocytosis by 3, and those showing slight phagocytosis by 1; the total is the numerical index, which corresponds exactly with the nomogram result.

CULTURE AND ANIMAL INOCULATION

Culture is understood to be the one definitive test for brucellosis, all important if positive but of no importance if negative. The need to carry out *repeated* cultures, especially in the chronic illness, to use only the most effective and complete of the special culture media, and methods, and to inoculate animals to supplement the cultural studies, under special circumstances, is still not fully appreciated. It is still the custom in some otherwise well run laboratories to discard cultures as negative if no growth is observed at the end of 10 to 21 days, to use routine instead of special methods (such as incubation in the presence of extra CO_2) and otherwise to frustrate the clinician's efforts to find laboratory proof of diagnosis. Many laboratories will take no active part in cultural attempts because of the danger to laboratory personnel. Such an evasion of duty is difficult to understand, although fear of dissemination of infection through animal inoculation is well founded.

Cultural methods have improved to some extent in the past ten years, but there is reason to hope for still better methods. Castaneda[15] offered some hope of simplification through the device of incorporating a vertical tryptose-agar slant in the side of a closed flask, at the bottom of which there is a mixture of tryptose broth and citrate to which the blood is added. This flask is incubated for not longer than 21 days and is turned on its side every 48 hours for the purpose of bathing the slant with the blood-broth-citrate mixture. If the organism is recoverable at all by this method, it usually will show fine grayish colonies within from 3 to 10 days. However, it is rarely that the *abortus* strain can be so recovered from the patient with a chronic infection, by this or other methods. There is not usually a bacteriemia in this phase of the illness; the *abortus* species grows with the greatest difficulty even in the presence of extra CO_2 Castaneda frequently was able to recover the *melitensis* species from acutely ill patients by this means. We have isolated *Brucella abortus* twice by this method; in both instances conventional methods for isolation of *Brucella* had failed.

It is often desirable to culture bile, urine, feces, spinal, synovial or prostatic fluid, and biopsy or operative tissue specimens, using special techniques[16] suitable to the material under study.

COMMENT AND SUMMARY

The available tests are inadequate for uniformly accurate diagnosis of brucellosis, especially of the chronic form. A more sensitive and comprehensive test is needed. It is to be hoped that a complement-fixation reaction for brucellosis can be developed that will fill this need.

Present laboratory methods are often unsatisfactory for the diagnosis of chronic brucellosis, as to sequence in which performed, technique and interpretation.

Regional Salmonella Centre

The New York State Health Department's Division of Laboratories and Research has been designated as a regional Salmonella Centre by WHO, to collaborate with the World Salmonella Centre at the State Serum Institute, Copenhagen, Denmark. The World Salmonella Centre, with the objective of collecting and identifying salmonella strains, was established by authority of The World Health Organization in 1948, under the direction of Dr. F. Kauffmann, in the Danish State Serum Institute. The New York State Laboratory in Albany was one of the first American laboratories to collaborate with Dr. Kauffmann before the second World War when an International Salmonella Centre, financed by the Commonwealth Fund, was established at the Danish State Serum Institute. Marion Coleman, senior bacteriologist in the Laboratories and Research Division, is in charge of the local regional Salmonella Centre.

Rabies Vaccine Encephalomyelitis in Relation to the Incidence of Animal Rabies in Los Angeles

CHARLES F. PAIT, M.D., AND HAROLD E. PEARSON, M.D.

Contagious Disease Unit and the Pathology Service of the Los Angeles County Hospital; and the Bacteriology Department, University of Southern California School of Medicine, Los Angeles, Calif.

THE field of communicable diseases has no more harassing problem than that of rabies. In areas where the disease is endemic the management of persons bitten by animals is unsatisfactory. Any advantage gained from the use of vaccine must be balanced against the chance of resultant, postvaccinal encephalitis.

The following indications for vaccination against rabies in the human being have been suggested[5]: (a) the biting animal is clinically rabid; or (b) is proved rabid by laboratory tests; (c) is suspected of being rabid; (d) in an endemic area, a stray animal escapes after biting; (e) an individual has handled an animal diagnosed as rabid and fresh abrasions of skin have been contaminated with saliva.

The number of persons who develop rabies after the bite of a rabid dog is not known with certainty but on the average may be 5 to 15 per cent[8]; if vaccine is given, the number may be reduced by half.[8] Too often, however, the situation involves categories (c) and (d) above. In such instances it is particularly necessary to estimate the likelihood of severe vaccination reactions. Table 1, as modified from McKendrick's figures of 1940 collected from worldwide sources, shows the incidence of paralytic accidents.[9] Such accidents are attended by a fatality rate of 5 per cent for the dorsolumbar type and 30 per cent for the Landry type of reaction.

Most of the vaccine used in this country is the Semple type and few data are available on the actual number of paralytic accidents here after use of such material. McCoy[6] reported an incidence of 1:2,900 among 17,600 treated persons but since 4 of the 6 reactions were fatal this rate probably is too low. Horack[3] recorded a rate of 1:1,200, 10 per cent fatal, among 24,000 treated persons.

TABLE 1

Incidence of Paralytic Accidents after Rabies Vaccine (from McKendrick, 1940)

Attenuated virus (Pasteur)	1:3,000
Diluted virus (Hogyes-Harris)	1:3,000
Phenol treated virus (Semple)	1:9,000
Ether treated virus (Alivisatos)	1:10,000
Heat treated virus	1:18,000

Some observations made on the incidence of postvaccinal encephalomyelitis in relation to the prevalence of animal rabies in Los Angeles City and County are presented here; 4 of the 9 cases listed were included in a previous report.[7]

Rabies is endemic in Los Angeles. There were (1946) approximately 3.5 million people living in an area of 4,000 sq. mi. in the county and almost 2 million in the 450 sq. mi. of the city proper. During the period of 25 years prior to 1947, there were 3,190 persons in the

TABLE 2

Cases with Reactions to Rabies Vaccine

40*	F	5	Bite	4	"	Encephalitis	3	Marked improvement. Poliomyelitis 11 years before.
25*	M	11 (2 ml.)	Bite, hand	10	"	Transverse myelitis	1	Moderate urinary retention. Ankle clonus.
24	F	5 (2 ml) 6 (1 ml.)	Bite on leg	11	"	Meningoencephalitis	1	Recovered.

* Previously reported [7]

city bitten by dogs proved to be rabid, but 3,560 persons received rabies vaccine. Of 22 deaths from rabies 14 had no vaccine. In 20 years of this period there were 14 cases of human rabies in the county exclusive of the city.

In the city approximately 90 per cent of the dogs over 4 months of age are licensed. On the basis of 125,000 licenses issued in 1946 the city's dog population exclusive of puppies may be estimated to be 140,000. On the average, a laboratory diagnosis of rabies is made annually on 40 dogs. Thus, at least one dog in 3,500 in the city becomes rabid. Since there are an unknown number of rabid dogs either not brought to examination or not detected if examined, the actual incidence is almost certainly higher. Approximately 150 rabid dogs per year are found in the county outside the city but the total dog population in the county is unknown.

Some 10,000 animal bites per year are reported in the city; these are almost all by dogs. Approximately 70 persons per year are bitten by known rabid animals; thus, one bite in 140 is by a rabid animal. On the basis of a 10 to 15 per cent human fatality rate following the bite of a rabid animal [8] the chance of getting rabies from known animal bites in the city of Los Angeles is 1:1,400 to 1:2,100. This does not include the numerous unreported bites which must occur.

During the 7 year period of 1940–1946, 9 cases of severe postvaccinal reactions, including one death, occurred among 5,500 persons receiving vaccine in the city and county, an incidence of 1:600. Particulars concerning these cases are shown in Table 2. All received Semple vaccine. Although 4 were given the product of one manufacturer, there is no reason to believe on the basis of total use of this particular product that it is unusually encephalitogenic.

DISCUSSION

Even the remote probability of developing rabies from a dog bite indi-

cated by the rough approximation made here will not alter the necessity of employing vaccine for any person bitten by an unidentified dog. Certainly, however, many persons receive vaccine who do not require it.

On the basis of data presented here and elsewhere it is apparent that the incidence of rabies vaccine encephalitis is a real contraindication to its indiscriminate use. Without discussing the theories regarding the etiology of this condition, it is likely that the incidence will be reduced markedly when a product more completely purified of brain tissue is produced; most present vaccines consist of approximately 10 per cent suspensions of rabbit brains.

There is ample evidence that rabies can be controlled in the absence of any considerable wild animal reservoir by control of dogs. Various plans and programs for control are now under discussion.[1-4] It is certain that none will be effective unless accepted by the public. This aspect is complicated in the Los Angeles area by the presence of a large and highly vocal group of dog fanciers who tend to resist all efforts to interfere in any way with the dog population. While such persons may reject programs based on protection of human beings they can scarcely fail to accept one designed primarily for the protection of dogs.

SUMMARY

In Los Angeles City and County approximately 200 rabid dogs are detected annually. There is only one human case per year but at least 800 persons are given rabies vaccine. The chance of acquiring rabies from known dog bites in Los Angeles is estimated to vary from 1:1,400 to 1:2,100.

There were 9 cases, one fatal, of postvaccinal encephalomyelitis among 5,500 treated persons, an incidence of 1:600.

An adequate rabies control program acceptable to the public and directed at the canine population is highly desirable.

A "Physical Growth Record" for Use in Elementary and High Schools

HOWARD V. MEREDITH, PH.D.

Iowa Child Welfare Research Station, State University of Iowa, Iowa City, Iowa

IN 1947 the writer was invited to prepare a "Physical Growth Record" for use in schools. The invitation came from the Joint Committee on Health Problems in Education of the American Medical Association and the National Education Association. Specifically, what the Joint Committee requested was a proposal for systematically recording and interpreting measurements of "height and weight" on school children—one that would lend itself to "wide distribution" and to sound yet ready use by the school nurse, the physical education instructor, or the one room rural school teacher.

A proposal was developed and prepared in the form of a 4 page booklet. This was submitted at a later meeting of the Joint Committee and, after preliminary favorable reaction, was referred to a subcommittee for detailed examination from the standpoints of format and content. A number of helpful suggestions were made by this subcommittee. Summarily, it was agreed by all parties concerned that (a) separate booklets would be prepared for boys and girls; (b) the charts on pages 2 and 3 of the booklets would begin at age 4 years and extend to age 18; (c) Drs. Dean F. Smiley and Fred V. Hein, on the basis of their practical experience with health education publications and school personnel, would make recommendations for improving the readability of pages 1 and 4 of the booklets; (d) the booklets would be sponsored and distributed by the Joint Committee; and (e) the writer would write an article describing the project more fully than was considered necessary in every booklet.

The booklets have been revised in accordance with the above agreements and are now available.* This paper is intended to constitute the writer's complete report on the project.

GENERAL FORM AND PURPOSE OF BOOKLET

Each booklet is designed for recording the growth in height and weight of a single child. Pages 1 and 4 of the booklet describe how to measure height and weight, how to register the measurements made, and how to interpret the status and progress information thus obtained. Pages 2 and 3 provide charts covering the age period 4 to 18 years for graphically depicting the growth of the individual in relation to growth norms. It follows that once a booklet has been assigned to a child it continues to be serviceable throughout the elementary and high school years.

The "purpose" of the booklet is stated to be that of supplying "interesting and helpful information" regarding the physical growth of school children. Near the top of page 1 space is afforded for indicating the child's name and date of birth. These are the only two personal items carried on the outside of the booklets. All of the physical

* They may be secured from the American Medical Association, 535 N. Dearborn St., Chicago 10, Ill., or the National Education Association, 1201 Sixteenth Street, N.W., Washington, D. C.

growth data collected on the child are recorded on the two inside pages—this gives the double advantage of protecting the data during filing and, whenever a booklet is open, of making visible the entire physical growth information accumulated on the child. There are separate forms carrying the captions "Physical Growth Record for Boys" and "Physical Growth Record for Girls."

HOW TO MEASURE HEIGHT AND WEIGHT

Weight—If available, use beam-type, platform scales. At the beginning of each examination period check the scales and, in the event they are out of balance, adjust them. Have the child remove shoes and sweater or jacket.* Request the child to stand in the center of the platform of the scales. As the weight record is read, make sure that the child's hands are not in contact with the head portion of the scales, with a wall, or with any other object. Determine weight to the nearest one-half pound.

Height—Use a measuring scale fixed in the upright position, and a wooden headpiece having two faces at right angles. The measuring scale may be an accurate yardstick, metric rod, steel tape, or paper scale.† Whatever type of scale is used, it should be firmly fastened either to a special upright board or (if there is no projecting wainscoting) directly to a smooth wall. While it is possible to use a chalk box as a headpiece, this is not recommended in a continuing school program. Secure a headpiece of more satisfactory design.‡

Measure height with shoes removed. Have the child stand with (a) heels, buttocks, upper part of back, and rear of head in contact with the wall or board; (b) heels nearly together but not touching each other; (c) arms hanging at the sides in a natural manner; and (d) head facing straight forward.** When the child is in position, place one face of the headpiece against the measuring scale and bring the other face down, keeping it horizontal, until it crushes the child's hair and makes firm contact with the top of the head. See that the heels are kept in contact with the floor, that the trunk is maintained in "non-slumped" contact with the measuring scale, and that no obstruction (e.g., clasp, braid, ribbon, or comb) prevents contact with the head. Take two separate height measurements on each child. Record height to the nearest one-fourth inch.

Some schools will find it convenient to measure children monthly or bi-monthly, while other schools will want a program more economical of time. It is recommended as a minimum procedure that each child is measured three times during the school year, in September, January, and May.

In so far as practicable, measure a child on or near the date of the month corresponding to his birth date. At the time of each measurement calculate the child's age. Do not consider age any more precisely than to the nearest month. That is, if a child is 4 years 8 months 5 days when measured, regard him as 4 years 8 months; if a child is

* The objective here is to reduce the child's clothing to a convenient minimum in order that the weight records will be as free as is considered expedient from augmentation and variation due to amount of clothing.

† An accurate scale printed on especially manufactured paper may be purchased from the Iowa Child Welfare Research Station, State University of Iowa, Iowa City, Iowa. Price $1.20.

‡ Specifications for such a headpiece may be obtained from the Bureau of Health Education of the American Medical Association, and an illustration will be found in *Univ. Iowa Stud. Ch. Wel.* 12, 2:109, 1936. (Succinctly, the shorter edges of two pieces of seasoned wood 7 inches by 5 inches are joined at right angles. Mounted within the 90° angle is a triangular strip of wood having an opening for insertion of the fingers. Many schools will find it possible to secure such an instrument through the co-operation of the manual arts instructor.)

** In anthropometric terms, the head should be oriented on the Frankfort Horizontal, *i.e.*, the tragus and the lower border of the bony orbit should lie in a plane parallel with the floor.

10 years 11 months and 21 days, regard him as 11 years.

HOW TO USE THE CHARTS

Figures 1 and 2 reproduce the charts from pages 2 and 3 of the booklets for boys (Figure 1) and girls (Figure 2). It is on these charts that the height and weight records of the individual child are registered. The charts are designed to portray both the status of the child at any age between 4 and 18 years and the progress of the child during any age period within the limits of 4 and 18 years.

Registering height and weight status—Assume that Figure 1 is to carry the record of Ted Stevens. Ted has just been examined; he weighs 44½ pounds, is 44 inches in height, and became 5 years of age yesterday. Refer to Figure 1: Locate age 5 along the top of the left-hand chart and 44 inches along the upper left-hand margin. Plot a point (place a dot) under the 5 and opposite the 44. Just above this dot on the HEIGHT portion of the chart write "44." Next, find age 5 along the bottom of the left-hand chart and 44½ lbs. along the lower left-hand margin. Plot a point above the 5 and approximately opposite 44½. Below this dot on the WEIGHT portion of the chart write "44½." With the completion of these directions, the height and weight status of Ted Stevens at age 5 years is fully registered. The status of Ted at other ages (or of any child) may be recorded in a similar manner.

Registering height and weight progress—Assume Ted is now 8 months older. His weight was taken at age 5 years 4 months but it was not possible at that time to get an adequate measurement of height due to a knee injury. The weight record was 46 lbs. Now, at 5 years 8 months, Ted weighs 48 lbs. and has a height of 45¾ in. Assume further that points representing weight at these two ages and height at the

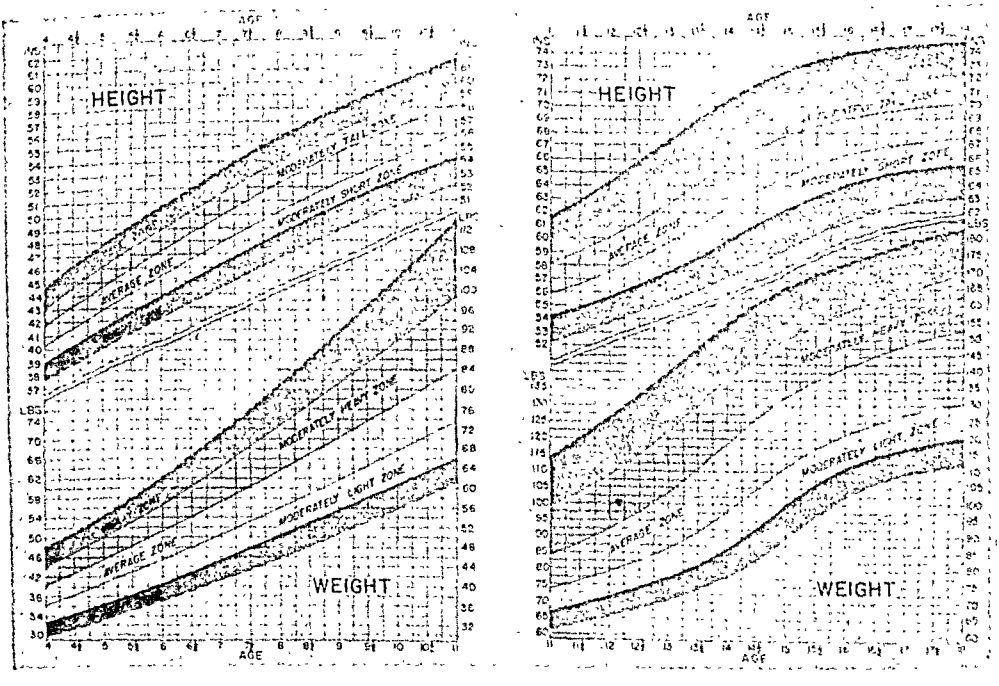

FIGURE 1—Reproduction of pages 2 and 3 of the "Physical Growth Record for Boys." Each chart is reduced from size 11 inches x 8 inches.

later age have been plotted on Ted's record (Figure 1). Having status materials at more than one age, it is now possible to derive curves of progress. Ted's height and weight progress over the age period from 5 years to 5 years 8 months is portrayed by drawing lines connecting (a) the two points on the height graph, and (b) the three points on the weight graph. Obviously by following the same general procedure, curves of progress may be obtained for any boy or girl over whatever period is desired within the age limits of 4 years and 18 years.

HOW TO INTERPRET THE CHARTS

After measuring a child and recording his or her measurements, one is confronted with the important problem of interpretation. What do the records indicate regarding the child's physical status and growth progress? What services will they perform in the evaluation of health?

Interpreting status—Ways in which the "Physical Growth Record" may be used for characterizing and appraising a child's status are as follows:

1. By following the recommended procedure of writing the measurement figures above or below each plotted point, there is available a ready description of any child's overall body size at each of the ages that measurements have been taken. For example, suppose Ted Stevens requests information on his size at age 5. His record describes him as weighing "44½" lbs. and as having attained a height of "44" in.

2. It will be seen that each of the HEIGHT graphs in Figures 1 and 2 depicts five normative zones—Tall, Moderately tall, Average, Moderately short, and Short. The zone in which a child's height point for a given age is located indicates his or her position with reference to the heights of others* of

* Explicitly, with reference to the heights of "white children of northwest European ancestry living under better-than-average conditions." This is discussed in a later section on "How the charts were obtained."

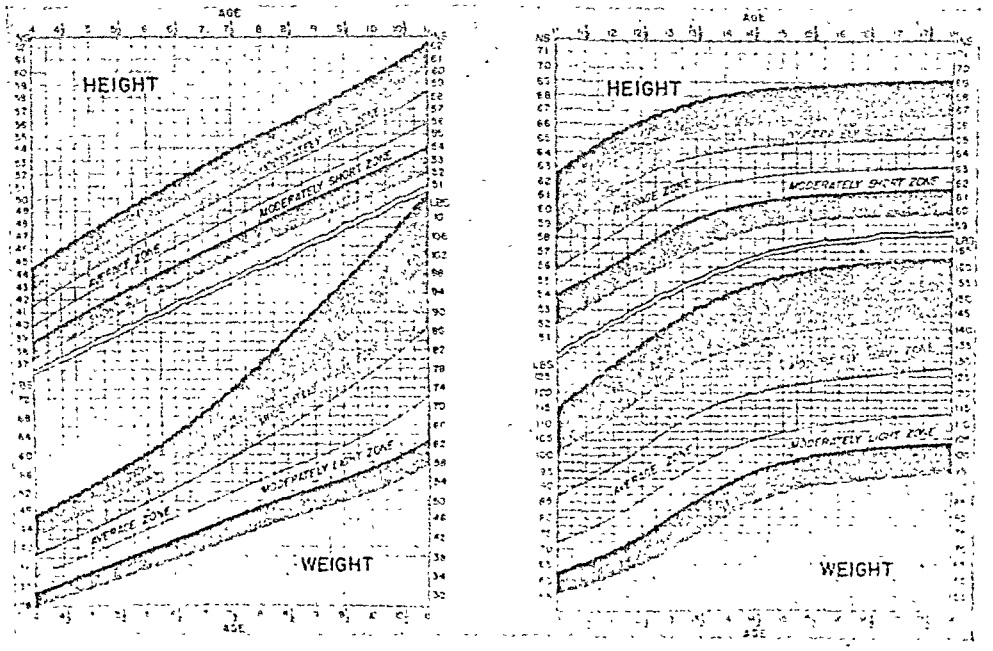

FIGURE 2—Reproduction of pages 2 and 3 of the "Physical Growth Record for Girls." Each chart is reduced from size 11 inches x 8 inches.

like sex and age. Shown on the WEIGHT graphs of Figures 1 and 2 are comparable normative zones designated Heavy, Moderately heavy, Average, Moderately light, and Light. The zone of location of a child's weight point for a given age similarly indicates his or her ranking in the distribution of weight at this age. The illustrative values given at age 5 show Ted to fall in the "Average zone" for both height and weight. Assume that Sam Weber and Doris Day also were examined at age 5: Sam's height was 47 in. and his weight 48 lbs.; the height and weight values obtained on Doris were 42 in. and 50 lbs., respectively. In relation to other children of like age and sex, Sam (referred to Figure 1) is "Tall" and "Moderately heavy," while Doris (referred to Figure 2) is "Moderately short" and "Heavy."

3. Whenever a child's height and weight points do not fall in corresponding zones (e.g., Tall and Heavy, Short and Light), there are two avenues of interpretation to be considered. That is, discrepancy or dissimilarity in zone placement (e.g., Moderately tall and Moderately light, Moderately short and Moderately heavy) may indicate normal stockiness or slenderness of build, or, may reflect an undesirable state of health. Suppose at the time of first measurement the height points of Bill Brown and Mary White each lie in the "Average zone," while the weight point for Bill lies in the "Heavy zone" and that for Mary in the "Light zone." Both children should be referred to a physician for examination. Mary may be a healthy girl of slender build or she may be "underweight" due to some unrecognized infection or nutritional deficiency. Similarly, Bill may be a healthy boy of stocky build or he may be "overweight" and in need of endocrine therapy, an especially prescribed diet, or a marked change in his daily regimen. The reciprocal roles of the "Physical Growth Record" and the physician will be readily appreciated here: The "Record" furnishes leads on possible deviations in health which serve to bring certain children to the physician's attention; the physician, in turn, utilizes his medical knowledge to determine which of the alternative interpretations of the "Record" appears the more sound.

Interpreting progress — Uses of the "Physical Growth Record" in describing and evaluating a school child's progress are:

1. The difference between a child's height measurements at two successive ages indicates the amount of augmentation or increase in height that has occurred during the interval. Likewise, by subtracting a boy's (or girl's) weight value for a given age from his (or her) weight value for a different age one obtains a figure showing the change in weight over the intervening period. On referring again to the illustrative materials for Ted Stevens, it will be found that during the age period 5 years to 5 years 8 months he gained 1¾ in. in height and 3½ lbs. in weight.

2. During childhood, the relation of an individual's height and weight curves to the appropriate normative curves affords information pertaining to satisfactoriness of growth. In the healthy child, over the period extending from age 4 in both sexes to age 9 for girls (Figure 2) and age 11 for boys (Figure 1), individual curves of height and weight run approximately parallel with their respective normative curves, i.e., individual height curves for boys follow the course of the boys' zone paths for height, individual weight curves for girls follow a course similar to that of the girls' zone paths for weight, and so forth. Consequently, if the height curve of Donna Davis (or Jim Jamison) falls along the middle of the "Moderately short zone" during the years from 4 to 7 and then tends abruptly toward

the "Short zone" (due, let us assume, to a gain between 7 and 7½ years of only ¼ to ½ in.), growth after 7 is "unsatisfactory" and warrants medical investigation. Although the weight curves of individual children are often less regular than their height curves, a weight curve which shows a downward dip (loss of weight), a plateau (failure to gain), or a sharp turn upward (excessive gain) should be considered suspect. The child should be weighed again the next day, or as soon thereafter as convenient: If the weight deviation is confirmed it should be regarded as sufficient cause for referring the child to a physician.

3. Beyond age 9 for girls and age 11 for boys, alignment of individual height and weight curves with the appropriate zone paths of Figures 1 and 2 permits sound appraisal of growth, providing allowance is made for variation in the timing of the so-called "adolescent spurt" or circumpubertal acceleration. There are wide individual differences in the age at which accelerated height and weight growth takes place; physically normal, healthy children in some instances will manifest more rapid growth by age 10 (girls) or 12 (boys), while in other instances rapid growth will not begin until after age 14 (girls) or 16 (boys).* Except for having to take into account this variation in age of the circumpubertal spurt, interpretations of physical growth progress are no different over the adolescent years than during the childhood years.

How does one make allowance for differences among individuals in the time at which the adolescent acceleration takes place? Assume that Nancy and Janice are practically alike in height and weight at each age from 4 to 9, but that Nancy begins rapid growth before 10½ and Janice not until after 13. Further, assume that Don and Dick consistently follow the course of their separate zone paths over the years from 4 to 11; but that Don begins rapid growth before 12½ and Dick not until after 15. Under conditions of normal, healthy growth, the height and weight curves of these four individuals will not follow the course of the zone paths within the age intervals 10 to 15 years (the girls) and 12 to 17 years (the boys). By ages 11 and 13 the curves of Nancy and Don respectively will be rising more rapidly than do the zone paths: As long as the height and weight curves for an individual are both following a like course, there is no need for concern. Over the years 10 to 13 and 12 to 15 the curves of Janice and Dick respectively will rise more gradually than do the zone paths: Again, as long as an individual is continuing steady growth in height and weight at his or her childhood rates, this growth should not be judged "unsatisfactory."

HOW THE CHARTS WERE OBTAINED

Method of construction—The charts (Figures 1 and 2) were constructed using percentile values obtained on a sample of the elementary and high school population. Specifically, the values used were the 1st, 10th, 30th, 70th, 90th, and 99th percentiles for height and weight at each successive annual age from 4 to 18. These six percentiles for each age and measurement were regarded as delimiting five zones.

The normative materials presented in the HEIGHT portions of the charts were drawn to the six series of height percentiles and are precisely described as follows: The "Short zone" is delimited by the 1st and 10th percentiles, the "Moderately short zone" by the 10th and 30th percentiles, the "Average zone" by the 30th and 70th percentiles, the "Moderately tall zone" by the 70th

* See Meredith, Howard V. Stature of Massachusetts Children of North European and Italian ancestry. *Am. J. Phys. Anthropol.* 24, 3:319–345, 1939.

and 90th percentiles, and the "Tall zone" by the 90th and 99th percentiles. Correspondingly, the normative materials presented in the WEIGHT portions of the charts were drawn to the six series of weight percentiles, the "Light zone" being bounded by the 1st and 10th percentiles, the "Average zone" by the 30th and 70th percentiles, and the "Heavy zone" by the 90th and 99th percentiles. In all of the graphs it will be seen that solid lines represent percentiles 10, 30, 70 and 90, while the two extreme percentiles are represented by dash lines.

A boy whose height point for a given age falls in the "Tall zone" will be recognized to have a height which exceeds that of not less than 90 per cent of the boys constituting the sample (i.e., he ranks among the tallest 10 per cent). In contrast, a boy whose height point falls in the "Short zone" obviously has a height less than that of 90 per cent or more of the boys making up the sample (i.e., he ranks among the shortest 10 per cent). A girl whose weight point for a given age lies in the "Average zone" has a weight which both exceeds and is exceeded by not less than 30 per cent of the girls' sample—she is of average weight in the sense of being among the middle 40 per cent of the group.

Source of data—Collection of the height and weight data from which the normative materials were derived took place during the years 1930 to 1945 * in the University of Iowa experimental schools, Iowa City, Iowa.† The subjects—there were between 100 and 200 of each sex examined at each year of age—were white children of northwest European ancestry living under better-than-average conditions from the standpoints of nutrition, housing, and health care. Explicitly: (a) over 90 per cent of the children were of northwest European ancestry, while only a scattering were of southeast European descent, and (b) approximately 40 per cent of the fathers were professional men (mainly members of the university faculty); 35 per cent business proprietors, managers, or skilled trade employees; 15 per cent farmers; and the remaining 10 per cent clerks, carriers, and semi-skilled laborers.

Are the normative materials presented in the charts appropriate for use in any North American school? More specifically, are they validly employed in schools whose pupils are drawn from the unskilled-laborer class, or from districts largely populated by families of Italian, Mexican, or Japanese ancestry? For purposes of growth and health appraisal, most school physicians and pediatricians consider it preferable to evaluate children of low socio-economic status in terms of norms obtained on groups for which nutrition and health care are known to be reasonably adequate. Charts based upon children representing a few other ethnic groups probably will be found desirable.‡ In the meantime, the presently available charts will be found of value with any group in evaluating growth progress.

A final word on the role of the particular school program here outlined. The reader is cautioned not to regard

* The inappropriateness of evaluating present-day children with norms based upon data collected earlier than the 1930's has been clearly shown. See Meredith, Howard V. Stature and Weight of Children of the United States. *Am. J. Dis. Child.* 62, 5:909–919, 1941; Meredith, Howard V., and Meredith, E. Matilda. The Stature of Toronto Children Half a Century Ago and Today. *Human Biol.* 16, 2:126–131, 1944.

† Some may question the extent to which norms based on Iowa children are suitable for use in other parts of North America. The evidence to date on this problem supports the view that the association between a child's height and weight and the geographic region in which he lives is so slight as to be inconsequential in the construction of school norms. See Meredith, Howard V. Stature and Weight of Children of the United States. *Am. J. Dis. Child.* 62, 5:927–932, 1941.
